(Submitted 19 June 2017 – Final revision received 7 December 2017 – Accepted 19 December 2017)

Abstract
Insufficient vitamin D status (serum 25-hydroxyvitamin D (S-25(OH)D) < 50 nmol/l) is common among immigrants living at the northern latitudes. We investigated ethnic differences in response of S-25(OH)D to vitamin D₃ supplementation, through a 5-month randomised controlled trial, in East African and Finnish women in Southern Finland (60°N) from December 2014 to May 2015. Vitamin D intakes (dietary and supplemental) were also examined. Altogether, 191 subjects were screened and 147 women (East Africans n 72, Finns n 75) aged 21–64 years were randomised to receive placebo or 10 or 20 µg of vitamin D₃/d. S-25(OH)D concentrations were assessed by liquid chromatography–tandem MS. At screening, 56 % of East Africans and 9 % of Finns had S-25(OH)D < 50 nmol/l. Total vitamin D intake was higher in East Africans than in Finns (24·2 (sd 14·5) v. 15·2 (sd 13·4) µg/d, P < 0·001). Baseline mean S-25(OH)D concentrations were higher in Finns (60·5 (sd 16·3) nmol/l) than in East Africans (51·5 (sd 15·4) nmol/l) (P = 0·001). In repeated-measures ANCOVA (adjusted for baseline S-25(OH)D), mean S-25(OH)D increased by 8·5 and 10·0 nmol/ml with a 10-µg dose and by 10·7 and 17·1 nmol/ml with a 20-µg dose for Finns and East Africans, respectively (P > 0·05 for differences between ethnic groups). In conclusion, high prevalence of vitamin D insufficiency existed among East African women living in Finland, despite higher vitamin D intake than their Finnish peers. Moderate vitamin D₃ supplementation was effective in increasing S-25(OH)D in both groups of women, and no ethnic differences existed in the response to supplementation.

Key words: Vitamin D; Vitamin D₃; 25-Hydroxyvitamin D; Randomised controlled trials: Supplementation

Serum 25-hydroxyvitamin D (S-25(OH)D) concentration is the most useful marker of vitamin D status (1). Sufficient vitamin D status (S-25(OH)D > 50 nmol/l) is essential for bone health, especially in the prevention of secondary hyperparathyroidism, which causes osteoporosis and fractures, and in reducing risk of falls (2,3). Vitamin D insufficiency (S-25(OH)D < 50 nmol/l) has also been associated with risk for many types of cancer and other chronic diseases (2,3), and is a public health problem, affecting populations living at northern latitudes, especially during winter (4,5). Nevertheless, the situation is not always the same between indigenous populations and immigrants. Vitamin D status in the majority of the native populations seems to be more satisfactory than among immigrants in the Nordic countries (6,7).

Diet, namely fatty fish, fortified dairy products, fortified fat spreads and cod liver oil, and vitamin D supplements remain the main sources of vitamin D for the northern populations during the winter months, when sun-induced vitamin D synthesis in the skin is limited (7–10). Unlike the indigenous populations, infrequent consumption of fatty fish and use of vitamin D supplements has been reported among immigrants of non-Western origin living in the Nordic countries (7,11). In contrast to the case with indigenous populations, nutritional factors may contribute to the high prevalence of vitamin D deficiency observed among immigrants in the Nordic countries, especially among women (11).

In particular, higher risk of vitamin D deficiency (S-25(OH)D < 30 nmol/l) among immigrants of African and Asian background residing in northern countries has been reported in several studies (6,8,12,13). Studies on skin colour and vitamin D synthesis have observed lower vitamin D status in individuals with dark skin than in those with lighter skin; skin pigmentation (melanin) interferes with vitamin D synthesis from UV-B (UVB) exposure (14,15). Wearing concealing clothing also contributes to increased risk of vitamin D deficiency (14,7). In Finland, high prevalence of S-25(OH)D < 30 and S-25(OH)D < 50 nmol/l

Abbreviations: 25(OH)D, 25-hydroxyvitamin D; IOM, Institute of Medicine; S-Ca, serum calcium; S-PTH, serum parathyroid hormone; S-Pi, serum phosphorus.

* Corresponding author: F. A. Adebayo, email folasade.adebayo@helsinki.fi
was observed in two recent studies of Somali\(^{(5,12)}\) and Kurdish immigrants\(^{(5)}\). In contrast to the immigrants, sufficient vitamin D status was reported for the majority of Finnish adults in 2012\(^{(10)}\). Insufficient S-25(OH)D concentrations have also been observed in other studies examining immigrants of East African\(^{(16–18)}\) and other ethnic origin\(^{(18,16,19)}\) in the Nordic countries.

Despite these disparities in vitamin D status between the dark-skinned and fair-skinned populations, similar vitamin D recommendations based on studies among Caucasian populations are currently followed among both groups in the United States and in the Nordic countries\(^{(1,2,27)}\). However, there may be differences in vitamin D requirement and metabolism between the different population groups\(^{(20)}\). Concerns about the vitamin D status and requirements of dark-skinned immigrants residing in the Western world, the impact of ethnicity and the need for dose–response studies were highlighted in the Institute of Medicine (IOM) Dietary Reference Intakes report\(^{(1)}\).

Hence, the primary objective of this 5-month randomised controlled trial (RCT) was to investigate ethnic differences in the response of S-25(OH)D to vitamin D\(_3\) supplementation over an extended winter period in women of East African and Finnish (Caucasian) descent. We also examined ethnic differences in vitamin D status with regard to S-25(OH)D concentrations and vitamin D intake from the diet and supplements in these two groups of women.

**Methods**

**Study design and subject population**

This intervention study was implemented within the European Union (EU)-funded research project ‘Food-based solutions for optimal vitamin D nutrition and health through the life cycle’ (ODIN; FP7-613977-ODIN; www.odin-vitd.eu). Specifically, the study was part of ODIN’s Work Package 6 with the overall objective of delivering the proof of efficacy and safety of food-based solutions to prevent vitamin D deficiency by focusing on EU-resident adults who are most at risk of vitamin D deficiency owing to skin colour, sun exposure practices or dietary habits.

The study was a 5-month, randomised, placebo-controlled, dose–response (0, 10, 20 µg/d vitamin D\(_3\)) trial conducted from December 2014 to May 2015. The study was tagged Marwo-D (the word was coined from the Somali word ‘Marwada’, which means lady, and the letter D, which stands for vitamin D). The participants were recruited from the Helsinki metropolitan area (latitude 60°N). The participants of East African descent were recruited from the Maamu and Health 2011 samples, and they were subsequently contacted by telephone. All women of East African descent were first-generation immigrants with Somali origin, dark-skinned and wore traditional clothing.

A total of 191 subjects were screened for eligibility. The inclusion criteria were female sex, Somali or Finnish origin, BMI ≤ 40 kg/m\(^2\) and S-25(OH)D concentration >30 but <100 nmol/l. The inclusion criteria for S-25(OH)D concentration was based on ethical viewpoint (not to include deficient subjects, who need supplementation) and ability to evaluate the response to supplementation (which may not be obvious among participants with higher S-25(OH)D concentrations). Exclusion criteria included pregnancy or breast-feeding during the study, a vacation in a sunny destination before or during the study, use of a tanning bed before or during the study and medication or illnesses that interfere with vitamin D metabolism. Medical history, S-25(OH)D concentration and other inclusion and exclusion criteria were assessed during screening in October/November 2014. Subjects who did not meet the inclusion criteria owing to S-25(OH)D concentration <30 nmol/l (i.e. vitamin D-deficient) received information on dietary and supplemental sources of vitamin D, and they were advised to contact their healthcare services for further medical actions. In addition, they were given either 10 or 20 µg of vitamin D\(_3\) supplements for daily use, depending on the severity of deficiency. Altogether, 147 women (77 % of those screened) – 72 (49 %) of East African descent and 75 (51 %) of Finnish descent, aged 21–64 years – met the inclusion criteria and were studied at the Calcium Research Unit of University of Helsinki, Finland. Participants’ recruitment and randomisation are presented in Fig. 1 (Consolidated Standards Of Reporting Trials (CONSORT) diagram).

The study was conducted according to the guidelines laid down in the Declaration of Helsinki, and all procedures involving human subjects were approved by the Coordinating Ethics Committee of the Helsinki and Uusimaa Hospital District. Written informed consent was obtained from all subjects. The consent form and the participant information sheet were provided in Somali and Finnish languages. The study was registered as a clinical trial on ClinicalTrials.gov (www.ClinicalTrials.gov; NCT02212223).

**Randomisation and intervention**

The East African and Finnish women who met the inclusion criteria were randomised into three supplementation groups: placebo or 10 or 20 µg vitamin D\(_3\)/d (Fig. 1). Participants were evenly randomised into intervention groups, for group similarities with respect to the distribution of S-25(OH)D, BMI, age, habitual vitamin D intake from supplements at screening and ethnicity. Altogether, 125 subjects (85 % of those randomised) completed the study and twenty-two subjects (15%) discontinued after randomisation. The reasons for discontinuation were as follows: withdrawal (n 8), lost to follow-up (n 8) and ineligible because of pregnancy (n 6). Supplements containing 10 or 20 µg of vitamin D\(_3\) per tablet and identical placebo tablets containing 0 µg were provided by Oy Verman Ab. Supplements and placebo tablets were kept in similar jars identifiable only by the subjects’ ID numbers. Each 10-µg vitamin D\(_3\) tablet
coincides with the Finnish national recommendation for daily vitamin D intake for the studied age group, whereas each 20-µg tablet is twice the Finnish national recommendation for daily vitamin D intake(24).

Each participant received a jar containing placebo or vitamin D₃ tablets at the baseline visit (in December) and subsequently at the midpoint visit (in February/March). They were advised to take one tablet daily and were given research diaries to keep a record of their study tablet use and occurrence of any side effects during the intervention period. At the midpoint and endpoint (in April/May) visits, compliance was calculated by counting the remaining tablets in the returned jars. The participants’ research diaries were evaluated at each visit during the intervention.
Participants were not restricted from taking their personal vitamin-D-containing supplements; those who used vitamin D supplements before the study were advised to continue in the same manner throughout the intervention period in order to avoid changes in their habitual vitamin D intake. Participants who had no previous personal vitamin D supplementation but wished to start were allowed to use supplements at doses \( \leq 10 \mu g \) of vitamin D/d. Possible changes in the use of personal vitamin-D-containing supplements were monitored during the intervention period.

**Background and dietary data collection**

Background data were collected from all participants through a detailed questionnaire either delivered via interview (women of East African descent) or self-administered (women of Finnish descent). Vitamin D supplementation practices were assessed based on how often vitamin-D-containing supplements were used, dosage and trademark; questions on general health included any experience of health problem and specific medication; and habitual sunshine exposure was measured by type of clothing worn outdoors in summer, and working hours and leisure time spent outdoors during summer. Weight and height were measured at screening and BMI was calculated as weight (kg)/height (m\(^2\)).

Habitual vitamin D intake was assessed in all participants, on the basis of a validated semi-quantitative interview-administered FFQ, at the baseline and endpoint of the intervention. The FFQ used in this study covered nine food groups, comprising altogether forty-six food items, considered important sources of vitamin D (Table 1). Vitamin D intake during the previous month was assessed with closed questions on consumption frequencies (daily, weekly, monthly, less often or not at all) and portion sizes (e.g. 1 glass or 1 piece). Open questions were asked with regard to use of fat (such as spread on bread, in cooking and baking). Information on brand name of food products was also included in the FFQ.

Interviews with women of Finnish descent were conducted in Finnish. Some of the women of East African descent were interviewed entirely in the Finnish language, whereas others were interviewed with translation by Somali-speaking research assistants, when necessary. A picture booklet of products for-""
of the distribution of wintertime serum 25(OH)D data from our previous study of white adult Finnish women\(^{27}\), we calculated that thirty-four volunteers per group should be recruited, with 90% power to detect a minimum of a 10 nmol/l increase in serum 25(OH)D between groups, within an ethnic group, at \(\alpha=0.05\). However, this number was increased to forty for each dose group (placebo, 10 and 20 µg/d in each ethnic group) to account for possible dropouts. A total of 240 women (120 in each ethnic group) were aimed to be enrolled, but the targeted sample size could not be reached because of the seasonal time frame (i.e. wintertime) of the study. Hence, we could not extend the recruitment period for more participants. We assumed that the distribution of wintertime serum 25(OH)D would be similar for non-white adult Finnish women and used similar numbers per group.

Normality of the distribution of variables was tested with the Kolmogorov–Smirnov test. ANOVA was used to assess differences in normally distributed variables in intervention groups within both ethnic groups, whereas differences in non-normally distributed variables were evaluated with a non-parametric test (Kruskal–Wallis). Comparison of variables between the two ethnic groups was performed with \(t\) tests (normally distributed variables) and the non-parametric Mann–Whitney \(U\) test (non-normally distributed variables). Repeated-measures ANCOVA was used to evaluate the effect of supplementation on S-25(OH)D, S-PTH, S-Ca and S-Pi in the two ethnic groups. In ANCOVA, the baseline S-25 (OH)D, S-PTH, S-Ca or S-Pi concentration was used as a covariate. Comparisons between intervention groups were carried out with contrasts. Results are presented as mean values and standard deviations, and in figures as means with their standard errors. All results were considered statistically significant at \(P<0.05\). IBM Statistical Package for the Social Sciences Statistics for Windows, version 21.0 (IBM Corp.), was used for statistical analysis.

In the analysis focusing on the effects of intervention, three East African subjects randomised to the group that received 20 µg/d (initial \(n\) 21) were moved to the placebo group (initial \(n\) 25) because one of the three participants stopped the supplementation after 4 d, and the other two participants did not take the supplement at all. Final analysis included only the participants who completed the intervention and had \(\geq90\%\) compliance rate with study supplementation in each group. Nevertheless, three participants were excluded from the analysis for the following reasons: pregnancy (\(n\) 1), kidney dysfunction (\(n\) 1) and sunburn (\(n\) 1). Subjects on medications owing to hypothyroidism (\(n\) 5) and type 2 diabetes (\(n\) 5) were included in the analysis because their exclusion had no significant effect on the results. Altogether, from 116 participants were analysed. Additional analyses were performed for the evaluation of vitamin D status in the two ethnic groups with regard to S-25(OH)D concentrations in all screened subjects (\(n\) 191) and vitamin D intake from the diet and supplements in all randomised subjects (\(n\) 147).

## Results

### Serum 25-hydroxyvitamin D at screening screened

We screened altogether 191 subjects (East African women \(n\) 104, Finnish women \(n\) 87). On the basis of the IOM thresholds for S-25(OH)D concentrations, 17% (\(n\) 18) and 39% (\(n\) 40) of the screened East African women were deficient (S-25(OH)D < 30 nmol/l) or had insufficient status (S-25(OH)D 30 to <50 nmol/l), respectively\(^{11}\). There was no vitamin D deficiency observed in Finnish women and the proportion of participants who had insufficient status (9%) (\(n\) 8) was lower than in East African women. Sufficient vitamin D status (S-25(OH)D \(\geq50\) nmol/l) was observed in 44% (\(n\) 46) of East African women and in 91% (\(n\) 79) of Finnish women. Higher concentrations (S-25(OH)D 75–125 nmol/l) were seen in 7% (\(n\) 7) of East African women and 33% (\(n\) 29) of Finnish women. S-25(OH)D concentrations above 125 nmol/l were observed in 5% (\(n\) 4) of Finnish women (Table 2).

### Characteristics of the participants in the intervention

Among the 147 randomised participants (East African women \(n\) 72, Finnish women \(n\) 75), the mean compliance with study supplementation in women of East African descent was 89% (\(n\) 54) and in women of Finnish descent it was 98% (\(n\) 71). The baseline mean S-25(OH)D concentrations were higher in Finnish women (mean: 60.5 (SD 16.3) nmol/l) than in East African women (mean: 51.5 (SD 15.4) nmol/l) (\(P=0.001\)) (data not shown). The characteristics of the 116 participants included in the final analyses are shown in Table 3. The intervention groups in each ethnicity did not differ from one another with regard to any background data. Nevertheless, women of East African descent differ from Finnish women in all characteristics, except for S-Pi concentrations.

### Baseline vitamin D intake and sources of vitamin D

Total vitamin D intake at baseline, as well as that from diet and supplements (where relevant) separately, and stratified by supplement non-use and voluntary supplement use (participants who used their personal supplements in addition to study supplements) are given in Table 4. Higher mean habitual vitamin D intakes from the diet (11.2 (SD 5.8) µg/d, \(P=0.005\)) and supplements (13.0 (SD 5.8) µg/d) were observed in East African women (\(n\) 72) than in Finnish participants (\(n\) 75) (Table 4). The proportions of voluntary supplement users in East African women and Finnish women were 88% (\(n\) 65) and 47% (\(n\) 35), respectively. Meanwhile, similar mean intakes from supplements were

observed among the voluntary vitamin D supplement users in both ethnic groups (East African women: 14.5 (SD 11.4) µg; Finnish women: 14.7 (SD 15.1) µg, P > 0.05) (Table 4). Participants using personal vitamin D supplements showed higher total mean vitamin D intake than those not using personal supplements (East African women: 26.0 (SD 13.9) µg; 8.7 (SD 7.4) µg, P = 0.002; Finnish women: 23.9 (SD 15.1) µg; 7.6 (SD 4.1) µg, P < 0.001) (Table 4). The proportion of participants attaining the daily recommended vitamin D intake of 10 µg (2,230) from diet and supplements was higher in East African women (83%) (n 60) than in Finnish women (55%) (n 41) (P = 0.003) (data not shown).

The contributory food sources to the mean daily intake of vitamin D for both East African women and Finnish women are presented in Fig. 2. The major source of vitamin D for the two groups of women was fortified fluid milk products, with higher intake in East African women (5.2 (SD 4.0) µg; Finnish women: 3.4 (SD 3.0) µg, P = 0.003). Similar vitamin D intake from fortified fat spread and fish was observed in both groups (P > 0.05).

**Effect of vitamin D supplementation on serum 25-hydroxvitamin D, serum parathyroid hormone, serum calcium and serum phosphorus**

After the 5-month intervention, the effect of vitamin D3 supplementation on S-25(OH)D among the 116 participants included in the analysis are shown in Fig. 3 (repeated-measures ANCOVA, adjusted for baseline S-25(OH)D concentration); compared with placebo, vitamin D supplementation with both 10- and 20-µg doses significantly increased S-25(OH)D concentration in both ethnic groups. No significant differences were seen between 10- and 20-µg dosages (P > 0.05) in either of the two ethnic groups. We observed no differences in the results when we excluded the three East African subjects who were moved from 20 µg to the placebo group. The results did not change after adjustment for personal supplement use, dietary vitamin D intake and BMI. Using a regression model, there was no significant difference in intake-S-25(OH)D response between women of East African descent and those of Finnish descent when baseline serum S-25(OH)D concentration was included as a covariate (P > 0.3; data not shown). The mean changes during the study period in the 10-µg D3 supplement groups for Finnish women and East African women were +8.5 (+14.1) and +10.0 nmol/l (+19.2%), respectively, and in the 20-µg D3 supplement groups they were +10.7 (+17.7) and +17.1 nmol/l (+32.7%), respectively. The mean changes in placebo groups for Finnish women and East African women were −7.8 (−13.0) and −2.3 nmol/l (−4.4%), respectively. Between the two groups of women, no significant differences were observed in response to vitamin D3 supplementation (P > 0.05) (Fig. 3). No significant effect of vitamin D3 supplementation on S-PTH, S-Ca or S-Pi was seen in either East African or Finnish women (P > 0.05) (repeated-measures ANCOVA, adjusted for baseline S-PTH/S-Ca/S-Pi, data not shown).

**Discussion**

This 5-month intervention was the first randomised controlled vitamin D dose–response study in East African and Caucasian women starting during the winter months, without natural UVB irradiation. The study demonstrated that supplementation with 10 and 20 µg of vitamin D3 was effective in increasing S-25(OH)D in both East African and Finnish women, whereas a significant decrease in S-25(OH)D concentrations occurred with placebo in both ethnic groups. No ethnic differences in S-25(OH)D
response to vitamin D₃ supplementation between the two ethnic groups were present.

To date, only a few dose–response vitamin D supplementation studies have been conducted in ethnically diverse populations.⁴⁻²⁰ Our study found no ethnic differences in S-25(OH)D response to vitamin D₃ supplementation between East African and Finnish women, consistent with earlier findings that the effect of dose on S-25(OH)D is independent of race.²⁸⁻³⁰ The two groups of women responded to vitamin D₃ supplementation in the same way.

Although our results did not change after adjustment for BMI, the higher BMI found in East African women might have contributed to their lower mean S-25(OH)D concentrations. Studies have shown an inverse association between BMI and S-25(OH)D concentrations as large fat mass reduces the bioavailability of synthesised vitamin D deposited in the body fat compartment.³¹⁻³⁵ Negative effects of BMI ≥ 25 kg/m² on S-25(OH)D have been described among African Americans.³²⁻³⁶ According to Drinic et al.,³⁴ lower S-25(OH)D concentration in obese individuals was attributed to volumetric dilution of ingested or cutaneous vitamin D in the large fat mass. On the other hand, inconsistent results on the effect of BMI on dose–response of S-25(OH)D to vitamin D supplementation have been reported in some studies.³⁷⁻³⁸ For instance, Grønborg et al.³⁹ found no association between body fat and vitamin D status, and also that body fat had no effect on the response to vitamin D supplementation. Genetic factors may also influence S-25(OH)D circulation.⁴⁰⁻⁴¹ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A similar situation with women of African ancestry may exist in our study.

Studies are needed to investigate association between genetic factors and S-25(OH)D among dark-skinned populations as the determinants of S-25(OH)D have been reported.⁴²⁻⁴³. A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³ A probable link between genetic background and response to vitamin D supplementation or dietary vitamin D exists; for instance, polymorphisms of the vitamin D receptor, vitamin D-binding protein or other genetic determinates of S-25(OH)D have been reported.⁴²⁻⁴³
vitamin D synthesis from UVB radiation during summer. Such absence of vitamin D production in the skin emphasises the relationship between the use of concealing clothes during summer and lower S-25(OH)D concentrations, especially among women\(^{4,7}\). According to Gallagher et al.\(^{29}\), absorption and metabolism of vitamin D in African-American and Caucasian women are similar. Hence, the reported lower S-25(OH)D concentrations in dark-skinned individuals probably occur owing to decreased formation of vitamin D in the skin\(^{4,30}\).

Besides oral vitamin D intake, this result suggests the presence of other factors (such as BMI and genetic factors) affecting S-25(OH)D concentrations in these women.

Some factors emerged as limitations against generalisation of this study’s findings. First, the baseline mean S-25(OH)D concentrations of the two groups of women included in the trial were quite sufficient (baseline mean S-25(OH)D > 50 nmol/l). This means that the results may be different in subjects with vitamin D deficiency. Second, the use of personal vitamin D supplement was not restricted during the intervention, and a high proportion of personal vitamin D supplementation was found in East African women. Third, the homogeneity of the participants with regard to sex (only women) limits the applicability of the results to men in the population. Fourth, although the FFQ used to assess the vitamin D intake of all subjects was pilotied among East African women, it was only validated among Finnish women (Caucasians)\(^{29}\). Thus, complete vitamin D intake in East African women might not have been evaluated. In addition, measurement error of the FFQ, such as over-reporting, might have contributed to the higher vitamin D intakes among East African women. The reported high consumption of fortified fluid milk may be culturally related to perceived status of milk as important staple diet in their home country.

One of the strengths of this research lies in the study design (randomised, placebo-controlled), which allowed for an objective evaluation of the effects of vitamin D\(_3\) doses on S-25(OH)D. Evaluation of compliance with vitamin D supplementation in this study is considered a strength, and dietary vitamin D intakes that were assessed at two different points probably proved the reliability of our data. Compliance rates with study supplementation, blood sampling and questionnaires, including FFQ, in both ethnic groups of women were high. Use of the participants’ preferred language, including translation (when necessary), during interviews enhances the quality of our data. Our first of its kind study provides up-to-date data on vitamin D intake and status in Finnish and East African women in Finland.

**Conclusions**

Supplementation with moderate vitamin D\(_3\) doses increased the S-25(OH)D concentrations in both East African and Finnish women during the 5-month intervention. Our study supports earlier findings that ethnicity has no effect on the response of S-25(OH)D to vitamin D\(_3\) supplementation. Future studies should focus on identifying the factors, other than dietary, associated with the greatest risk of vitamin D insufficiency in dark-skinned populations.

**Acknowledgements**

The authors thank all volunteer subjects who participated in the Marwo-D intervention study. The authors are grateful to the researchers in the Maamu study for their advice on participants’ recruitment. The authors also thank technician Anu Heiman-Lindh for laboratory analyses at the University of Helsinki. The authors acknowledge Oy Verman Ab, Kerava, Finland, for providing supplements and placebo tablets.

This work was carried out within ODIN WP6 (www.odin-vitamin D.eu), which is funded by the European Commission (grant agreement 613977). The funder was not involved in the design, analysis or writing of this article.

C. L.-A. and K. D. C. are grant holders. F. A. A., S. T. I., T. Ö., E. S., E. M. S., M. E. and C. L.-A. were involved in the design of the study. F. A. A., T. Ö., E. S. and E. M. S. collected the data. K. D. C. was responsible for the S-25(OH)D analyses at the University College Cork, Ireland. F. A. A. drafted the manuscript and performed the statistical analysis with the guidance of S. T. I. Evaluation of the results and comments on and critical reviews of the manuscript were carried out by S. T. I., M. E. and C. L.-A. All co-authors reviewed and approved the final draft of the manuscript.

The authors declare that there are no conflicts of interest.
