# Tunable Quasi-Reflectionless Bandpass Filters Using Substrate Integrated Coaxial Resonators

Kunchen Zhao, Student Member, IEEE, Roberto Gómez-García, Senior Member, IEEE and Dimitra Psychogiou, Senior Member, IEEE

Abstract— This brief reports on the electromagnetic (EM) design and the practical development of frequency-reconfigurable quasi-reflectionless bandpass filters (BPFs) using substrate integrated coaxial (SIC) resonators. The filter concept is based on in-series-cascaded quasi-reflectionless stages that are shaped by a first-order bandpass section and two resistively-terminated first-order bandstop sections. For the first time, we explore the realization of these filters using tunable SIC resonators that exhibit high quality factor (Q) and can be widely tuned with commercially-available linear piezoelectric actuators. Synthesized examples alongside various EM design and practical integration aspects are discussed in detail. The concept is experimentally validated at S-band through the manufacturing and testing of two reconfigurable (one-stage and two-stage) prototypes.

*Index Terms*— Absorptive filter, coaxial filter, frequencytunable filter, quasi-reflectionless filter, reflectionless filter.

## I. INTRODUCTION

ESPITE in their infancy, reflectionless or absorptive bandpass filters (BPFs) are recently being explored as a compact reflection cancellation mechanism for multi-stage RF front-ends (e.g., in instrumentation systems [1] and in harmonic radars [2]) in which reflected RF signals deteriorate the dynamic range of the overall RF system by creating spurs, standing waves, and unwanted oscillations [3]. Unlike traditional reflective-type BPFs that present a high reactive impedance in their stopband regions, reflectionless BPFs are designed with a 50- $\Omega$  impedance for both their passband and stopband ranges. Thus, their direct integration in the RF frontends of reflection-sensitive systems promises significant size and performance advantages when compared to conventional reflection-cancellation approaches in which bulky ferrite-based circulators (e.g., [4] and [5]) or power-hungry transistor-based non-reciprocal components (e.g., [6]) are employed.

Reflectionless BPFs are typically constructed by adding resistively-terminated bandstop filtering networks at their input ports [7]-[10]. As an example, an input reflectionless tunable BPF with the co-designed function of a power divider is shown

Fig. 1. SIC-resonator-based quasi-reflectionless BPF concept. (a) EM model of the one-stage quasi-reflectionless BPF comprising one bandpass section and two bandstop sections. Frequency tuning is achieved by altering the resonator capacitance through contactless metallic tuners (blue patches). (b) CRD: black circles are resonating nodes, gray circles are non-resonating nodes, and white circles are the source, load, and resistively-terminating nodes. (c) Bottom view showing design parameters. (d) Detail of the tunable SIC resonator. Design parameters are (units in mm):  $l_a = 9.84$ ,  $l_{b1} = 6.7$ ,  $l_{b2} = 7.9$ ,  $l_c = 11$ ,  $g_a = 0.28$ ,  $g_b = 0.26$ ,  $g_c = 0.58$ ,  $d_m = 1.4$ ,  $r_a = 2$ ,  $r_b = 6$ ,  $d_{gap} = 1$ , and  $\theta_{slot} = 80^\circ$ ; a width of w = 2 mm is used in all GCPW TLs and resistive loads  $R_s = 50\Omega$  are employed.

in [7]. However, tuning is achieved using trimmer capacitors that are not electronically tunable. Frequency-tunable reflectionless BPF using lumped-element components [9] or planar microstrip resonators [10] have also been proposed,

where the frequency agility is obtained by using surface mount varactors. Despite these configurations being frequency tunable, they are only able to suppress reflections at a single port of the filter. Symmetric reflection-cancellation methods have been demonstrated in [11]-[15]. Nevertheless, most of them rely on specific component element values or use tightlycoupled components, whose characteristics are directly related to the design frequency and the passband bandwidth (BW). As an example, a GaAs-MMIC-based fully-reflectionless BPF is demonstrated in [11] with high selectivity and large rejection ratio. However, it requires unrealistic characteristic impedance values if implemented with transmission-line-based components. In [12], a symmetrical reflectionless BPF is reported with a wide absorptive BW. Nevertheless, it is realized using tightly-coupled gap resonators, which are difficult to be tuned. In addition, all of the aforementioned examples are based on low-quality-factor (Q) lumped element or planar components that result in high in-band insertion loss (IL) (e.g., 3 dB in [11] and 2.4 dB in [13]), limited power-handling capability, and are mostly frequency static.

In order to reduce the IL and maintain a relatively compact volume, substrate-integrated-waveguide-(SIW)-based resonators and filters have been extensively studied as a suitable alternative to traditional planar filter technologies [16], [17]. In particular, substrate-integrated-coaxial-(SIC)-resonator-based filters have been attracting significant interest due to their compact size and the potential for frequency tuning. Although these concepts have been widely explored as reflective BPFs [18]-[21], bandstop filters (BSFs) [22]-[23], and multi-band filters [24], yet there is no reported work on SIC-resonatorbased reflectionless BPFs.

Considering the aforementioned limitations, this brief reports on the design and practical development of frequencyreconfigurable quasi-reflectionless BPFs using compact SIC resonators. The proposed integration scheme is based on inseries-cascaded stages that exhibit two-port quasi-reflectionless characteristics. The quasi-reflectionless behavior is achieved by adding a bandstop filtering network with a 50- $\Omega$  resistive load at the input/output ports. Frequency agility is added by altering the capacitance of the SICs using commercially-available piezoelectric linear actuators. The proposed concept is validated through the manufacturing and testing of a one-stage and a two-stage prototypes.

## **II. THEORETICAL FOUNDATIONS**

#### A. Filter Concept and Operating Principles

The details of the quasi-reflectionless SIC-resonator-based BPF concept are shown in Fig. 1 through the conceptual 3D drawing (and EM simulation model) of a single-stage configuration and its corresponding normalized coupling routing diagram (CRD). It is based on three sections, namely a bandpass section that comprises one resonator (resonant node 2) and two inverters  $K_A$ , and two resistively-terminated bandstop sections that each consists of one resonator (resonant node 4 or 7) and three inverters  $K_B$  and  $K_C$ . For the symmetric quasi-reflectionless BPF response to be obtained, the transfer functions of the bandpass and the bandstop sections need to be complementary and fulfill  $K_C^2 = K_A^2 \cdot K_B^2$  [12], provided that all resonators are synchronously tuned at the normalized frequency  $\Omega = 0$ .

An example of synthesized power transmission and reflection responses of the normalized CRD in Fig. 1(b) is illustrated in Fig. 2(b) for the case of  $K_A=1$ ,  $K_B=1$ , and  $K_C=1$ , which results in quasi-reflectionless symmetric characteristics with < -15 dB of input reflection across the entire frequency range. To increase the selectivity and power reflection, multiple replicas of the one-stage configuration can be in-series cascaded, and the overall response of the filter can be calculated

Fig. 3. Detail of the bandstop section that comprises a slot-coupled SIC resonator and a GCPW TL. (a) EM model. (b) Circuit equivalent that consists of an LC tank, and a TL followed by a transformer representing the  $K_{\rm C}$  inverter.

Fig. 4. (a) Simulated  $Q_e$  and  $d_{gap}$  as a function of  $\theta_{slot}$  and  $Z_C$  for the SIC resonator frequency to be equal to 3 GHz.  $Q_e$  is calculated at port 1 of Fig. 3(a). (b) Phase response of an ideal one-port network that consists of one resonator and an ideal  $K_c$  inverter and EM-simulated phase response of the coupled resonator section in Fig. 3(a) for  $\theta_{slot} = 80^{\circ}$  and different  $l_c$ , where  $l_c = 16$  cm is 90° long at 3 GHz.

as  $S_{21}^{N-\text{stage}}(\Omega) = \left[S_{21}^{\text{one-stage}}\right]^N$ , where N is the number of stages. An example case of a two-stage normalized CRD alongside its corresponding synthesized responses is shown in Fig. 2. It should be noticed that the inverters of the bandstop section that are shared between adjacent stages need to be normalized as  $K'_{\rm B} = \frac{K_{\rm B}}{\sqrt{2}}$ . As also shown in Fig. 2(b), BW control can be obtained by altering  $K_A$ .

## B. Practical Design Aspects Using SIC Resonators

To practically realize this filter, a high-Q and compact integration concept using capacitively-loaded SIC resonators and grounded coplanar waveguide (GCPW) transmission-line (TL) inverters is employed as shown in Fig. 1(c). The filter design starts by creating the tunable resonator using the SIC integration scheme in Fig. 1(d), whose fundamental operational principal is discussed in [21]. In particular, the resonator is embedded in a dielectric substrate in which Cu-platted via holes form its cavity walls and the inner conductor of the coaxial. The capacitive loading is materialized by: i) a capacitive ring between the upper end of the inner conductor and the cavity ground  $(g_{cap})$  and ii) a Cu-metalized PCB disk that is positioned on top of the resonator at a distance  $d_{gap}$  to the upper cavity wall

as shown in Fig. 1(d). Therefore, frequency tuning is achieved by altering  $d_{gap}$ , which changes the capacitance of the resonator. The RF signal in each resonator is inserted through slot openings in the bottom ground plane of the filter.

Having designed the tunable SIC resonators, the bandstop and the bandpass sections are designed as follows. In the bandstop section, the  $K_{\rm B}$  inverter between nodes 1 and 3 are implemented with a 90°-long GCPW line with characteristic impedance  $Z_{\rm B} = Z_0 / K_{\rm B}$  (50  $\Omega$  for the case of  $K_{\rm B} = 1$ ), and the resistively terminated K<sub>B</sub> inverter between nodes 3 and 5 loaded with  $Z_0$  is materialized by a single resistor with an equivalent resistance  $R_{\rm T} = Z_{\rm B}^2/Z_0$  for size compactness. The detail of the  $K_{\rm C}$  inverter and its equivalent circuit are shown in Fig. 3(a) and (b). It is comprised of two parts, namely a GCPW TL with  $Z_{C}$ and length  $l_{\rm C}$  (<90° at  $f_c$ ) and a slot opening  $\theta_{\rm slot}$  that couples the RF signal into the SIC resonator. Both of the slot and GCPW TL contribute to the external coupling factor  $Q_{e}$  (calculated at port 1 in Fig. 3) as shown in Fig. 4. To determinate the value of  $Z_c$  and  $\theta_{slot}$ , for a given  $Q_e = 1/(K_c^2 \cdot FBW)$  (e.g., for FBW =6% and  $K_{\rm C} = 1.2$ , and  $Q_e = 11.5$ ), EM-simulation-based parametric studies need to be performed. As shown in Fig. 4(a), by increasing  $\theta_{slot}$ ,  $Q_e$  decreases. However, this also causes the resonant frequency of the SIC to decrease, which can be counteracted by altering  $d_{gap}$ . With  $Z_C$  and  $\theta_{slot}$  chosen,  $l_c$  needs to be defined so that the combined  $K_C$  inverter functionalizes

3D-printed fixture

the 90° phase inversion at port 1. As shown in Fig. 4(b), a 90°long TL (defined at 3 GHz) results in an ideal phase inversion at 2.82 GHz, which is lower than the expected 3 GHz. This is attributed to the induced phase shift from the slot opening, which in turn requires  $l_c$  to be shortened. It should be noted that  $l_c$  does not affect the resonating frequency or  $Q_e$ .

#### **III. EXPERIMENTAL VALIDATIONS**

Considering the aforementioned design aspects, a one-stage and a two-stage SIC-based BPFs were designed for a center frequency of 3 GHz and as wide as possible tuning range in the S-band. They were implemented on a Rogers TMM3 substrate (thickness H = 3.125 mm, dielectric constant  $\epsilon_r = 3.32$ , loss tangent tan  $\delta = 0.002$ , and copper thickness  $t = 17\mu$ m). The SIC resonator tuner was implemented by a copper-plated circular disk that was attached on the top of a commerciallyavailable digitally-controlled linear actuator from New Scale Tech. [25]. To enable their integration, a multi-part 3D printed fixture was designed and manufactured and is shown in Fig. 5 alongside with the filter assembly during RF testing.

The manufactured one-stage quasi-reflectionless SIC-based BPF is shown in Fig. 6(a) and (b). It was characterized with a Keysight N5224A PNA and exhibits the following RF measured performance [see Fig. 7]:  $f_c$  tuning between 2.68-3.40 GHz (1.3:1), minimum in-band IL between 1.10-2.78 dB, 3-dB fractional BW (FBW) between 5.18%-6.76% and effective quality factor  $Q_{eff}$  = 180 at 3 GHz A comparison with one of its corresponding EM simulated states is shown in Fig. 7(a), which appears to be in a good agreement. Figs. 8 and 9 respectively demonstrate the two-stage prototype and its RF measured performance that can be summarized as follows:  $f_c$  tuning

Fig. 8. (a) Front side of the two-stage BPF prototype. (b) Back side of the two-stage BPF prototype.

Fig. 9. (a) RF-measured and EM-simulated S-parameters of the two-stage prototype at 3 GHz. (b) RF-measured S-parameters while tuning the capacitively-loaded SIC resonators of the BPF.

between 2.60-3.35 GHz, minimum in-band IL between 3.14-3.72 dB, 3-dB FBW between 4.23%-5.37% and  $Q_{eff}$ = 150 at 3 GHz. A comparison with one EM simulated state is also provided in Fig. 9(a), which exhibits a fair agreement between the simulation and measurement result, successfully validating the proposed SIC-resonator-based quasi-reflectionless BPF concept. It should be noticed that the S<sub>11</sub> and S<sub>22</sub> are not identical in the two-stage case due to the geometrical asymmetry (i.e., resistor location) in the shared bandstop This article has been accepted for publication in a future issue of this journal, but has not been fully edited. section. Nevertheless, a quasi-reflectionless behavior is achieved at both ports. The discrepancy between the measured and simulated loss is due to manufacturing tolerances and assembly errors, as well as the surface roughness and loss of the Cu disks. A comparison of the proposed concept with state-ofthe-art planar and lumped element reflectionless BPFs is provided in Table I. As shown, the proposed concept is the only symmetric quasi-reflectionless BPF that is based on a high-Qintegration scheme using 3D SIC resonators. Furthermore, it exhibits lower IL and wider tuning range than its lumped element and planar counterparts in [9] and [13].

## IV. CONCLUSION

This brief has presented the design, manufacturing, and testing of SIC resonator-based BPFs with symmetric quasireflectionless characteristics. Frequency agility and size compactness are obtained by tuning the capacitively-loaded SIC resonators with commercially-available linear actuators. Various EM design and integration aspects were discussed in detail. The operating principles of the proposed tunable quasireflectionless SIC-resonator-based BPF were experimentally validated at S-band through the manufacturing and testing of a one-stage and a two-stage prototypes.
