Justice considerations in climate research

In the format provided by the authors and unedited

SUPPLEMENTARY INFORMATION

SUPPLEMENTARY METHODS and DISCUSSION including SUPPLEMENTARY FIGURES S1-S2 and SUPPLEMENTARY TABLES S1-4

S1. The Shared Socioeconomic Pathway (SSP) narrative elements

The SSP elements that are used to sketch out five different future trajectories are shown in Table S1, for more details please see.[1]

Table S1. SSP narrative elements from Tables 1-3 from[1].

SSP Element
Demographics: growth, fertility, mortality, migration, urbanization (type/level)
Human Development: education, health investments, access to health facilities, water, sanitation, gender equality, equity, social cohesion, societal participation
Economy & lifestyle: growth per capita, inequality, international trade, globalization, consumption & diet
Policies & Institutions: international cooperation, environmental policy, policy orientation, institutions
Technology: development, transfer, energy tech change, carbon intensity, energy intensity
Environment & natural resources: fossil constraints, environment, land use, agriculture

S2. Literature Review

We conducted a structured review (Figure S1) of two literature databases[2–4] on the Shared Socioeconomic Pathways (SSPs) which have been used by research to follow consistent data and storylines in their analyses.

The two databases contain close to 2,500 articles for the timeframe 2014-2019 (Version 1) and 2020-2021 (Version 2). We referred to the available coding for SDGs, health, poverty & livelihoods as well as impacts/vulnerability and emissions. For our focused analysis on justice, we used the following search terms for **TITLE** and **ABSTRACT** to scan the databases to identify articles that **explicitly** worked on justice issues.

- Fair*
- Just*
- Distribut*
- Equit*
- Equal*

This led to 533 articles (~21%). After a screening of the abstracts, 456 were discarded for various reasons [e.g., duplicates; the search terms yielded words with irrelevant meanings (especially true for the search term “just*”), the paper did not cover the topic itself but only claimed importance of the subject, the paper did not refer to mitigation scenarios, or natural climate impacts were studied (especially true for the term “distribut*”)].

This led to 77 papers (~3%) that entered the next step of coding according to our framework [see Excel file and Table S4]. Database version 1 covered six years and led to 43 unique entries, while version 2 covered two years and led to 34 entries.

As we were interested in aspects of wellbeing, we also scanned papers which were categorized under poverty and livelihoods. Some had already come up in the initial search, but 37 additional papers were identified, 24 were then reviewed in detail, and the remaining 13 turned out to be irrelevant. Coding according to our framework was not possible for many patterns and indicators. These articles informed our paper but did not enter in the analysis of studies that “explicitly relate to aspects of climate justice”. The same applies to papers covering different SDGs and SSP narratives.

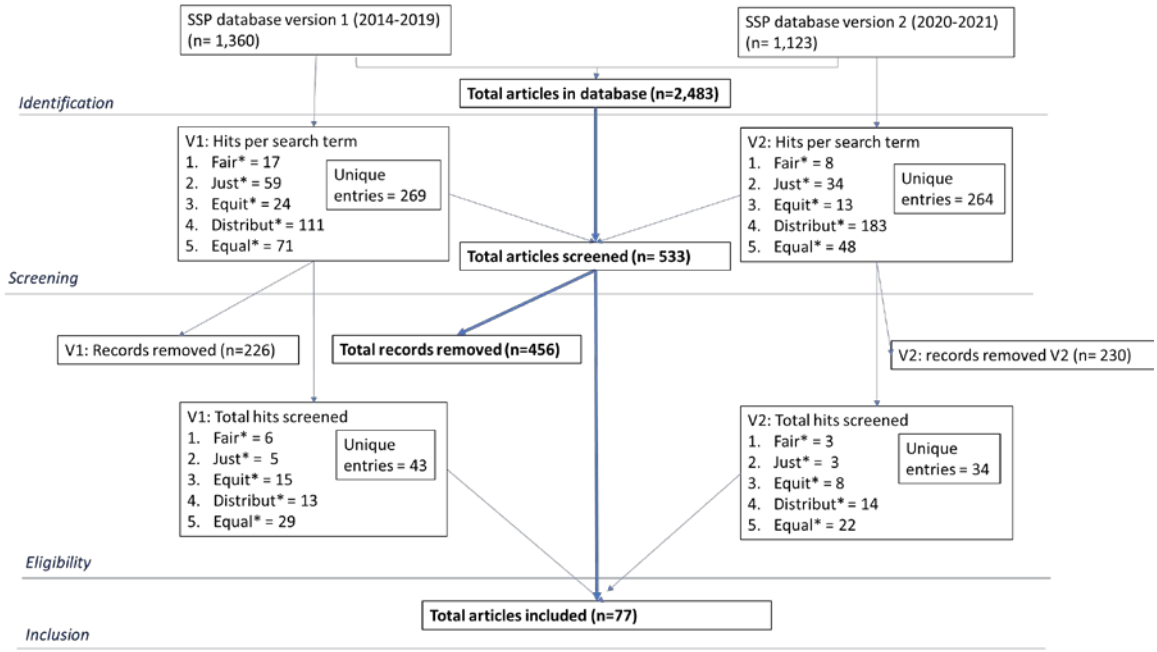

Figure S1. Literature Review. Unique entries, some appeared in several searches.

Figure S2 shows the cumulative spread of search terms for the included articles form the two literature databases, with equit* and equal* being more prevalent.

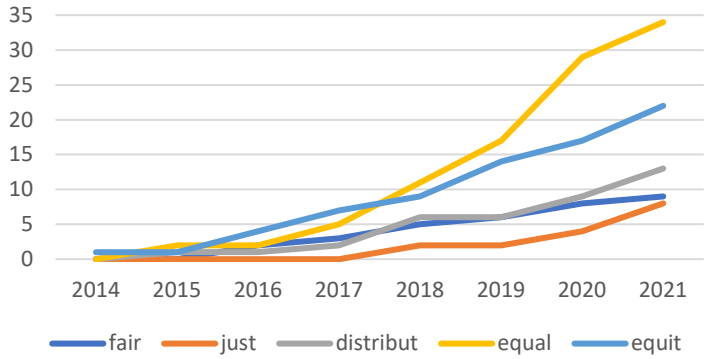

Figure S2. Hits per search term of included articles over the timeframe 2014-2019 (database version 1) and 2020-2021 (database version 2) from the two literature databases[2–4] on the Shared Socioeconomic Pathways. Search terms: fair*, just*, distribut*, equit*, equal*.

In the next step, we map articles to our justice framework to identify the dominant justice patterns, metrics (and indicators), and implementation approaches. Table S2 provides an overview per pattern and indicator. Table S3 by implementation approach and indicator.

Table S2. Patterns per indicator covered in the literature reviewed.[1]

Utilitarian/prioritarian	19	12	7	1	1	**28**
Egalitarian	21	11	5	2	1	**29**
Sufficientarian	8	7	5	4	0	**18**
Limitarian	0	0	0	2	0	**2**
Mix	5	0	1	1	0	**7**
Total	**34**	**35**	**19**	**10**	**4**	**Total**
	GHG emissions	GDP	Energy	Food	Health	

[1] Note: the number of unique studies does not match the total as some studies involved several patterns (for several metrics) and scenarios, and some studies involved patterns that were not easily defined.

Table S3. Implementations approaches per indicator covered in the literature reviewed. [1]

1. Scenario/model design & data input	5	8	10	5	1	**21**
2. Scenario output post-processing	14	4	0	0	0	**18**
3. Scenario evaluation	3	3	3	1	0	**6**
4. Methodological/ qualitative discussions	5	8	3	1	1	**12**
5. SSP-based projections	5	8	2	2	2	**14**
Total	**34**	**35**	**19**	**10**	**4**	**Total**
	GHG emissions	GDP	Energy	Food	Health	

For Figure 2 in the main text and Table S2 and S3, we coded our entries as follows (see Table S4 in Excel sheet), reflecting the following patterns.

- Utilitarian/prioritarian = For example, studies that follow cost-effective optimization.
- Sufficientarian = For example, studies that accounted for decent living services.
- Limitarian = For example, studies that introduced a cap on consumption.
- Egalitarian = For example, studies that reflected inequality indices (e.g., Gini).

The scenarios studies we cover are multidimensional and generally follow a narrative that aims to reflect the potential development of society. Such developments do not reflect stylized futures that map perfectly onto one of the theoretical patterns described here. In this light, we classify and categorize scenarios by how closely their key characteristics reflect a pattern, even if there are minor theoretical inconsistencies. However, we acknowledge that it is difficult to attribute a pattern to a particular trajectory. We conclude that future research could formalize the analysis of how to extract patterns from quantitative scenarios , an area in which we believe philosophers and scientists could engage in valuable interdisciplinary work.

Many studies on burden sharing follow the IPCC equity principles. which we matched to the patterns of distributive justice as follows:

- cost effectiveness = utilitarian
- capacity/ability to pay = utilitarian/prioritarian
- right to development = sufficientarian
- equal per capita = egalitarian
- responsibility/polluter pays = N.A. (related to corrective justice, not distributive justice)
- grandfathering/sovereignty = N.A. [we did not treat this as a pattern of justice, since we were concerned with intratemporal patterns, not intertemporal patterns (which we treat as part of transitional justice); furthermore, many philosophers deny that there are justice-based reasons to adopt grandfathering principles [5,6]]

Implementation

1. Scenario/model design & data input:
    - Considering justice elements at the level of input (exogenous) assumptions or key assumptions driving the model results
    - For example, assumptions about regional convergence of GDP per capita, food consumption, final energy consumption levels etc.
2. Scenario output post-processing (i.e., LCA, carbon budget equity assessments)
    - Additional indicators are derived, for example, to assess the implications of certain technology trajectories on jobs, water consumption, land use etc.
3. Scenario evaluation

- No new indicators are derived but scenarios are assessed across many indicators (typical for example for the growing feasibility assessments or technology growth-rates)
- Scenario benchmarking to other lines of evidence

4. Methodological/conceptual (qualitative/narrative) discussions
    - For example, discussion about how the objective function could be adjusted but not the implementation
5. SSP based projections
    - This could be considered as additional post-processing method but based on SSP scenarios and projections
    - For example, studies estimating implications of different SSP trajectories for hunger
