ABSTRACT

Gold and silver complexes containing the monophosphane 1-PPh₂-2-Me-1,2-C₂B₁₀H₁₀ with different coordination numbers (2, 3) have been synthesized. Complexes [M(7,8-(PPh₂)₂-C₂B₉H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)] [M = Ag, Au] and [Au₂(μ-1,n-C₂B₁₀H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂] (n = 2, 12). Solid-state pyrolysis of [AuCl(1-PPh₂-2-Me-C₂B₁₀H₁₀)] and [Au₂(μ-1,12-C₂B₁₀H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂] under air and of solutions of [AuCl(1-PPh₂-2-Me-C₂B₁₀H₁₀)] deposited on silicon and silica at 800°C results in single crystal Au confirmed by diffraction and SEM-EDS. The morphology of the pyrolytic products depends on the thermolytic conditions and different novel 3-D superstructures or microcrystals are possible. We also propose a mechanism for the thermal conversion of these precursors to structural crystalline and phase pure materials. The presence of the carborane-monophosphane seems to originate quenching of the luminescence at room temperature in complexes [Au₂(μ-1,n-C₂B₁₀H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂], compared with other [Au₂(μ-1,n-C₂B₁₀H₁₀)L₂] (L = monophosphane).

INTRODUCTION

The monophosphane 1-(PPh₂)-2-Me-C₂B₁₀H₁₀, has been selected for this work due to its electron withdrawing capacity and chemical and thermal stability (both due to the skeleton based on the carborane cluster). The aim is to analyse the influence of this ligand in the products and structures resulting from the pyrolysis of gold complexes and in the luminescence properties of the complexes synthesized.

From the synthetic point of view we have taken into account the varieties of complexes reported with carborane monophosphanes.^{1,2} They consist in mononuclear complexes of stoichiometry: [AuClL](7-(PPh₂)-8-R-C₂B₉H₁₀)(PPh₃) L = (PCl^tBu)-C₂B₁₀H₁₁, 1-(PPh₂)-2-Ph-C₂B₁₀H₁₀ and P(CH₂-1-C₂B₁₀H₁₁)₃ (Fig. 1a and 1b)¹ and [Au(7-(PPh₂)-8-R-C₂B₉H₁₀)(PPh₃)] (R = Me, Ph, SBz, SEt).^{2a-2c} Mixed gold–rhodium or gold–ruthenium metallocarborane complexes (Scheme 1)^{2b} and the metallorhodium complex [Ag₂(thf)₂(OTf)₂{1-(PPh₂)-3(η⁵-Cp*)-3,1,2-RhC₂B₁₀H₁₀}₂] in which no Rh···Ag metallic interactions are present and the two silver atoms are bridged by two triflate ligands.^{2d} We have focus our attention in two- and three-coordinated gold and silver complexes.

Figure 1. Gold complexes with carborane monophosphanes

And have also synthesised organometallic derivatives, taking into account that organometallic complexes with C(carboranyl)-Au σ-bonds are well represented for the *ortho*- isomer,³ but they are almost unknown for the *meta*- isomer.⁴ Recently we reported the synthesis and crystal structure of the first example of such complexes with the *para*-carborane isomer.^{3g}

Scheme 1

The carborane cage in dicarba-*closo*-dodecaboranes displays high stability under many reaction conditions, which include oxidizing agents, alcohols or strong acids. The thermal and thermo-oxidative stabilities of carborane-containing polymers are also interesting and useful properties. Pyrolysis of such polymeric materials has been previously described and the salient features of the process have been established.⁵ The formation of ceramic materials (including C-Si-B), micro or nanoscale BPO₄ and SiC/B₄C/C nanocomposites has been reported. We have found that gold derivatives as *gem*-[N₃P₃(O₂C₁₂H₈)₂(OC₅H₄N-4{Au(C₆F₅)}₂)]₂ and its polymer [NP(O₂C₁₂H₈)]_{0.7}{NP(OC₅H₄N-4{Au(C₆F₅)}₂)_{0.3}}]_n are useful precursors for nanostructured Au.⁶ The pyrolysis of the carborane polyphosphazene {[NP({OCH₂})₂C₂B₁₀H₁₀)]_{0.5}[NP({OCH₂})₂C₂B₉H₁₀•NBu₄)]_{0.5}}]_n, affords nanostructured BPO₄.^{8d} We have also analysed the deposition of micro- and nanoscale gold and silver structures after direct pyrolysis on silicon and silica surfaces.⁷ Thus we are interested in the resulting material and the final structures obtained upon pyrolysis of carborane derivatives with gold content.

Luminescence has revealed as a property shown for several complexes and useful in medicine both in diagnosis (for immunoassay) and in photodynamic therapy.⁸ Also, in the design of volatile organic compound (VOC) detectors, as the presence of organic molecules may change the emission maxima or even lead to luminescence quenching. On the other hand, complexes with a triplet excited state may be used as phosphor dopants in the fabrication of phOLEDs (phosphorescent organic/organometallic light emitting diodes).⁹ Taking into account these facts, the work has been completed with the analyses of the luminescent properties of the complexes synthesized, as dicarba-*closo*-dodecaboranes themselves and their derivatives, including different coordination complexes and the effect of the incorporation of fluorescent molecules in the carborane cage have been reported.^{3g,10} As part of our previous studies we have analysed different mono [M(7-(PR₂)-8-Ph-C₂B₉H₁₀)L]^{10s,10t,10v} (M = Au, Ag, Cu; L = monophosphane) and dinuclear [Au₂(μ-1,n-C₂B₁₀H₁₀)(PR₃)₂] (n = 2,7,12)^{3g} systems with carborane backbones. In this work we are interested in the effect the electron withdrawing carborane-monophosphane 1-(PPh₂)-2-Me-C₂B₁₀H₁₀ in the luminescent properties of these systems.

Thus, in this work we present different gold and silver complexes with the 1-(PPh₂)-2-Me-C₂B₁₀H₁₀ monophosphane. Many of the properties of the carborane derivatives, some

of which were mentioned above, are enhanced by increasing the boron content. Thus, in most cases, the synthesis has been directed to obtain molecules with high boron content. We also report the influence of the carborane monophosphane in the luminescent properties of mononuclear $[M(7,8-(PPh_2)_2-C_2B_9H_{10})(PR_3)]$ and dinuclear $[Au_2(\mu-1,n-C_2B_{10}H_{10})(PR_3)_2]$ ($n = 2, 12$) gold systems and the thermolysis of gold complexes containing carborane ligands, in order to elucidate if the resulting material will be nanostructured Au, BPO_4 or both, what its crystal structure will be, and whether or not the resulting material is a complex composite. To the authors' knowledge, this is the first dedicated investigation of the pyrolysis into monomeric (not polymeric) carborane materials that includes the *para*-isomer, as opposed to previous thermolytic studies using *ortho*-carborane derivatives. Thus these complexes allow the evaluation of the effect of the nature of the carborane precursor ie.: one gold atom by one carborane unit with two gold atoms by three carborane units, on the phase, morphology and size of the pyrolytic products.

EXPERIMENTAL

General comments

$[AuCl(tht)]^{11}$ ($tht = SC_4H_8$) and the monophosphane¹² 1-(PPh_2)-2-Me- $C_2B_{10}H_{10}$ were synthesized according to published procedures. Other reagents and solvents were used as received. When anhydrous solvents were needed they were obtained from the purification solvent (SPS) PS-MD-5 Innovative Technology, Scharlab. Solution ^1H and $^{31}P\{^1H\}$ NMR spectra were recorded using BrukerAvance 400 and Bruker ARX 300 spectrometers. The chemical shifts (δ) were referenced to $SiMe_4$ (^1H , external) or 85% H_3PO_4 (^{31}P , external). Steady-state photoluminescence spectra were recorded with a Jobin-Yvon Horiba Fluorolog FL-3-11 spectrometer.

$[AuCl(1-PPh_2-2-Me-C_2B_{10}H_{10})]$ (1): To a dichloromethane solution (15 mL) of 1- PPh_2 -2-Me- $C_2B_{10}H_{10}$ (0.2 mmol, 68.5 mg) $[AuCl(tht)]$ (0.2 mmol, 64.1 mg) was added. The mixture was stirred for 1 h and then the solution was concentrated to c.a. 3 mL under reduced pressure. Precipitation of **1**, as a white solid was afforded by addition of *n*-hexane. Yield: 97%. **Analytical data** (%), calculated for $C_{15}H_{23}AuB_{10}ClP$: C, 31.34; H, 4.03; found: C, 31.31; H, 3.96. **^1H NMR** ($CDCl_3$, ppm): 0-3 (m, br, 10H, BH), 2.39 (s, 3H, Me), 7.61-7.69 (m, br, 5H, Ph), 8.17-8.23 (m, br, 5H, Ph). **$^{31}P\{^1H\}$ NMR** ($CDCl_3$, ppm): 50.9 (s). **I.R.** (cm^{-1}): $\nu(BH) = 2570$ (st), $\nu(AuCl) = 327$ (st).

[Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)(tht)]OTf (2): A dichloromethane solution (15 mL) of 1-PPh₂-2-Me-C₂B₁₀H₁₀ (0.2 mmol, 68.5 mg) was added to a freshly prepared solution of [Au(tht)₂]OTf (0.2 mmol) ([Au(tht)₂]OTf was synthesized *in situ* from 0.2 mmol of [AuCl(tht)] (64.1 mg), AgOTf (56.5 mg) and tht (17.63 μ L) in dichloromethane). The mixture was stirred for 1.5 h and concentrated under reduced pressure. Compound **2**, as a white solid, was obtained by addition of *n*-hexane. Yield: 84%. **Analytical data** (%), found: C, 30.44; H, 4.15; S, 8.73; calculated for C₂₀H₃₁AuB₁₀F₃O₃PS₂: C, 30.93; H, 4.02; S, 8.26. **¹H NMR** (CDCl₃, ppm): 0-3.5 (m, br, 10H, BH); 2.27-2.31 (m, br, 4H, CH-tht), 2.34 (s, 3H, Me), 3.66 (m, br, 4H, CH-tht), 7.70 (br, 5H, Ph), 8.18-8.23 (m, br, 5H, Ph). **³¹P{¹H} NMR** (CDCl₃, ppm): 54.4 (s). **¹⁹F NMR** (CDCl₃, ppm): -78.1 (s, OTf). **I.R.** (cm⁻¹): ν (BH) = 2578 (st), $\nu_{as}(\text{SO}_3)$ = 1287 (st), $\nu_{sim}(\text{CF}_3)$ = 1223 (st), $\nu_{as}(\text{CF}_3)$ = 1162 (st), $\nu_{sim}(\text{SO}_3)$ = 1025 (st).

[Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂]OTf (3): Method A: A dichloromethane solution (20 mL) of 1-PPh₂-2-Me-C₂B₁₀H₁₀ (0.4 mmol, 137.6 mg) was added to a freshly prepared solution of [Au(tht)₂]OTf (0.2 mmol) (synthesized *in situ* as described for complex **2**). The mixture was stirred for 2 h. The solution was then concentrated under reduced pressure and the product, as a white solid, was obtained by addition of *n*-hexane. **Method B:** To a dichloromethane solution (20 mL) of [Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)(tht)]OTf (**2**) (0.2 mmol, 155.3 mg) 1-PPh₂-2-Me-C₂B₁₀H₁₀ (0.2 mmol, 68.5 mg) was added. Then the procedure was similar to that described in method A. Yield: 78%. **Analytical data** (%), found: C, 35.64; H, 4.11; S, 3.94; calculated for C₃₁H₄₆AuB₂₀F₃O₃P₂S: C, 36.11; H, 4.49; S, 3.11. **¹H NMR** (CDCl₃, ppm): 1-3 (m, br, 20H, BH); 2.15 (s, 6H, CH), 7.76 (br, 10H, Ph), 8.20 (br, 10H, Ph). **³¹P{¹H} NMR** (CDCl₃, ppm): 62.4 (s). **¹⁹F NMR** (CDCl₃, ppm): -78.3 (s, OTf). **I.R.** (cm⁻¹): ν (BH) = 2586 (st), $\nu_{as}(\text{SO}_3)$ = 1271 (st), $\nu_{sim}(\text{CF}_3)$ = 1252 (st), $\nu_{as}(\text{CF}_3)$ = 1156 (st), $\nu_{sim}(\text{SO}_3)$ = 1028 (st).

[M(7,8-(PPh₂)₂-C₂B₉H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)] M = Ag (4), Au (5): A solution (20 mL) of 1-PPh₂-2-Me-C₂B₁₀H₁₀ (0.2 mmol, 68.5 mg) in ethanol was added to a solution of [MX(1,2-(PPh₂)₂-C₂B₁₀H₁₀)] (0.2 mmol, MX = Ag(OTf) 153.9 mg; AuCl 149 mg) in ethanol. The mixture was refluxed for 1.5 h and a white (**4**) or yellow (**5**) solid appeared which was collected by filtration and washed with *n*-hexane. **4.** Yield: 87%. **Analytical data** (%), found: C, 51.53; H, 5.10; calculated for C₄₁H₅₃AgB₁₉P₃: C, 51.72; H, 5.61. **¹H NMR** (CDCl₃, ppm): -2.08 (s, br, 1H, B-H-B), 0-3 (m, br, 19H, BH), 1.90 (s, 3H, Me), 6.92-7.24 (v.m, br, 10H, Ph), 7.30-7.64 (v.m, br, 15H, Ph), 7.90-7.94 (m, br, 5H, Ph). **³¹P{¹H} NMR** (300 MHz, CDCl₃, ppm): δ_A = 40.9, δ_X = 19.6; J[¹⁰⁹Ag-P_A] 583.4 Hz, J[¹⁰⁹Ag-P_X] 383.4 Hz,

J_{AX} 63.4 Hz. **I.R.** (cm^{-1}): $\nu(\text{BH}) = 2542$ (st). **5.** Yield: 87%. **Analytical data** (%), found: C, 47.13; H, 5.10; calculated for $\text{C}_{41}\text{H}_{53}\text{AuB}_{19}\text{P}_3$: C, 47.29; H, 5.13. **^1H NMR** (CDCl_3 , ppm): -2.12 (s, br, 1H, B-H-B), 0-3 (m, br, 19H, BH); 1.68 (s, 3H, CH), 7.15-7.22 (m, br, 4H, Ph), 7.30-7.46 (v.m, br, 14H, Ph), 7.55-7.63 (m, br, 8H, Ph), 7.91-7.96 (m, br, 4H, Ph). **$^{31}\text{P}\{^1\text{H}\}$ NMR** (CDCl_3 , ppm): AB_2 system $\delta_A = 68.8$, $\delta_B = 60.0$; $J_{AB} = 138.1$. **I.R.** (cm^{-1}): $\nu(\text{BH}) = 2541$ (st).

[Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)(1,2-(PPh₂)₂-C₂B₁₀H₁₀)]OTf (6): A solution (20 mL) of [Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)(tht)]OTf (7) (0.2 mmol, 155.3 mg) in dichloromethane was added to a solution of 1,2-(PPh₂)₂-C₂B₁₀H₁₀ (0.2 mmol, 102.4 mg) in dichloromethane. The mixture was stirred for 1.5 h. The solution was then concentrated to c.a. 3 mL under reduced pressure and the product, as a pale yellow solid, was obtained by addition of *n*-hexane. Yield: 75%, white colour. **Analytical data** (%), found: C, 41.81; H, 4.51; S, 2.57; calculated for $\text{C}_{62}\text{H}_{84}\text{Au}_2\text{B}_{30}\text{F}_6\text{O}_6\text{P}_4\text{S}_3$: C, 42.10; H, 4.20; S, 2.67. **^1H NMR** (CDCl_3 , ppm): 1-3.5 (m, br, 20H, BH); 2.29 (s, 3H, CH), 7.42-7.90 (v.m, br, 25H, Ph), 8.16-8.21 (m, br, 5H, Ph). **$^{31}\text{P}\{^1\text{H}\}$ NMR** (CDCl_3 , ppm): $\delta_A = 70.9$, $\delta_X = 57.8$; $J_{AX} = 146.25$ Hz ($\Delta\nu \gg J$). **^{19}F NMR** (CDCl_3 , ppm): -78.1 (s, OTf). **I.R.** (cm^{-1}): $\nu(\text{BH}) = 2575$ (st), $\nu_{\text{as}}(\text{SO}_3) = 1272$ (st), $\nu_{\text{sim}}(\text{CF}_3) = 1222$ (st), $\nu_{\text{as}}(\text{CF}_3) = 1153$ (st), $\nu_{\text{sim}}(\text{SO}_3) = 1028$ (st).

[Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)(PPh₃)]OTf (7): A solution (20 mL) of [Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)(tht)]OTf (2) (0.2 mmol, 155.3 mg) in dichloromethane was added to a solution of PPh₃ (0.2 mmol, 52.4 mg); in dichloromethane. The mixture was stirred for 1.5 h. The solution was then concentrated to c.a. 3 mL under reduced pressure and a white solid was obtained by addition of *n*-hexane. The solid contains a mixture of complexes 7 and the homoleptic species [Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂]OTf and [Au(PPh₃)₂]OTf. The following NMR data correspond to 7: **^1H NMR** (CDCl_3 , ppm): 0.5-3 (m, br, 10H, BH), 2.27 (s, 3H, CH), 7.51-7.73 (v.m, br, 15H, Ph), 8.16-8.21 (m, br, 10H, Ph). **$^{31}\text{P}\{^1\text{H}\}$ NMR** (CDCl_3 , ppm): AB system; $\delta_A = 43.1$ (d, PPh₃), $\delta_B = 61.1$ (d, PPh₂), $J_{AB} = 325.5$ Hz. **^{19}F NMR** (CDCl_3 , ppm): -78.1 (s, OTf).

[Au₂(μ -1,*n*-C₂B₁₀H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂] [*n* = 2, (8); *n* = 12, (9)] To a 0 °C diethyl ether solution (20 mL) of *ortho*- or *para*-carborane 1,*n*-(CH)₂B₁₀H₁₀ (*n* = 2, 12; 28.4 mg, 0.2 mmol), under argon atmosphere, Li^{*n*}Bu (*n*-hexane solution 1.6 M, 0.38 mL, 0.6 mmol) was added and the mixture was stirred for 1.5 h (8) or 2.5 h (9). The solution was warmed up to room temperature and [AuCl(1-PPh₂-2-Me-C₂B₁₀H₁₀)] (0.35 mmol, 201 mg) was added. The

suspension was stirred for 4.5 h (**8**) or 1.5h (**9**) and the remaining solid filtered through *celite*. The filtrate was concentrated under reduced pressure and n-hexane was added to obtain a pale yellow solid, which was collected by filtration. **8**: Yield: 87%. **Analytical data (%)**, found: C, 31.87; H, 4.89; calculated for $C_{32}H_{56}Au_2B_{30}P_2$: C, 31.47; H, 4.62. **^1H NMR** ($CDCl_3$, ppm): 1-3 (m, br, 30H, BH); 2.36 (s, 6H, Me); 7.43-7.46 (m, br, 5H, Ph), 7.62 (m, br, 5H, Ph), 7.99-8.04 (m, br, 10H, Ph). **$^{31}P\{^1H\}$ NMR** ($CDCl_3$, ppm): 54.5 (s). **I.R.** (cm^{-1}): $\nu(BH) = 2562$ (st). **9**. Yield: 87%. **Analytical data (%)**, found: C, 31.19; H, 4.18; calculated for $C_{32}H_{56}Au_2B_{30}P_2$: C, 31.47; H, 4.62. **^1H NMR** ($CDCl_3$, ppm): 1-3 (m, br, 30H, BH), 2.32 (s, 6H, CH), 7.55-7.63 (m, br, 12H, Ph), 8.04-8.10 (m, br, 8H, Ph). **$^{31}P\{^1H\}$ NMR** ($CDCl_3$, ppm): 53.4 (s). **I.R.** (cm^{-1}): $\nu(BH) = 2580$ (st).

Crystallography

Crystals were mounted in inert oil on glass fibers and transferred to the cold gas stream of Xcalibur diffractometer equipped with a low-temperature attachment. Data were collected using monochromated Mo $K\alpha$ radiation ($\lambda = 0.71073 \text{ \AA}$). Absorption corrections: SADABS.¹³ The structures were refined on F^2 using the program SHELXL-97.¹⁴ Selected details of the data collection and refinement are given in Table 1. CCDC 962746-962747 contain the supplementary crystallographic data for complexes **5** and **8**, respectively, reported in this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via [www.ccdc.cam.ac.uk.data-request/cif](http://www.ccdc.cam.ac.uk/data-request/cif).

Casting and pyrolysis

The pyrolysis experiments were conducted by pouring a weighed portion (0.05–0.15 g) of the precursor **1**, **9** into aluminum oxide boats that were placed in a furnace (Daihan oven model Wise Therm FHP-12) under a flow of air, heating from 25°C to upper temperature limits of 300°C, and then to 800 °C, followed by annealing for 2-4 h and at rates of 10 °C min⁻¹ in each case.

A drop of CH_2Cl_2 solution containing the mixtures (solutions/suspensions in the range $1 \times 10^{-3} - 5 \times 10^{-4} \text{ g/mL}$) of **1** was cast over either a silicon or oxidized silicon surface and the solvent evaporated. The Si or SiO_2 wafer (with 400 mg of thermally grown oxide) was subsequently pyrolyzed at 800°C using a predefined temperature program (Daihan oven model FHP-12) where the polymer samples were heated at a rate of 10°C min⁻¹ from room temperature to 800°C under a constant air flow of 120 mL min⁻¹ and subsequently annealed for 2 h. The resulting depositions give a

uniform areal coverage for each mixture.

Electron microscopy and energy dispersive X-ray analysis

Scanning electron microscopy (SEM) and energy dispersive X-ray analysis (EDX) were acquired with a Hitachi S4800 and SU70 FESEM operating at 10 kV equipped with an Oxford Instruments X-max 50 mm² solid-state EDX detector for elemental line scanning and mapping. Suitably dispersed powders were also analyzed on holey carbon Cu grids by

transmission electron microscopy (TEM) using a JEOL 2100F FEGTEM operating at 200 kV.

RESULTS AND DISCUSSION

Synthesis and characterization

Reaction of the monophosphane 1-PPh₂-2-Me-C₂B₁₀H₁₀ with [AuCl(tht)] or [Au(tht)₂]⁺ in 1:1 molar ratio leads to the formation of [AuCl(1-PPh₂-2-Me-C₂B₁₀H₁₀)] (**1**) and [Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)(tht)]OTf (**2**), respectively. If the reaction with [Au(tht)₂]OTf is carried out in 2:1 molar ratio compound [Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂]OTf (**3**) is obtained (Scheme 2).

In the I.R. spectra of complexes **1-3** the ν (BH) vibration appears between 2563 and 2606 cm⁻¹, in addition the ν (Au-Cl) vibration appears in **1** and the absorptions attributed to the presence of the triflate anion in **2** and **3**. A broad signal from ca.1 to 3 ppm is assigned to the BH hydrogen atoms of the carborane moiety in the ¹H NMR spectra. The resonance corresponding to the methyl group of the carborane cage appears at about 2 ppm. Compound **2** also displays two multiplets due to the hydrogen atoms of the that ligand. The three complexes display one singlet in the ³¹P{¹H} NMR spectra between 50.9 and 62.4 ppm.

The three-coordinated complexes [Ag(7,8-(PPh₂)₂-C₂B₉H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)] (**4**) and [Au(7,8-(PPh₂)₂-C₂B₉H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)] (**5**), which contain a *closo*-carborane-monophosphane and a *nido*-carborane-diphosphane may be obtained from the reaction of [Ag(OTf)(1,2-(PPh₂)₂-C₂B₁₀H₁₀)] or [AuCl(1,2-(PPh₂)₂-C₂B₁₀H₁₀)], with the monophosphane in refluxing ethanol (Scheme 1). During these reactions the partial degradation of the carborane cluster of the diphosphane and coordination of the gold or silver center to the monophosphane takes place. The degradation of the carborane cage has been shown to be favored upon coordination of the diphosphane to a metallic center.¹⁵ This idea could support the fact that it is the diphosphane and not the monophosphane which is partially degraded in the reaction. Nevertheless we have carried out the reaction of complex [AuCl(1-PPh₂-2-Me-C₂B₁₀H₁₀)] (**1**) with the diphosphane 1,2-(PPh₂)₂-C₂B₁₀H₁₀ in refluxing ethanol and the result of the process is the formation of **5**. Thus, in both experiments it is the diphosphane which is partially degraded. Partial degradation of carborane clusters may take place with lewis bases like alkoxides, amines, fluorides and even heterocyclic carbenes and consist on a nucleophilic attack of one of the two boron atoms nearest to the carbon ones. In alcoholic media the RO⁻ is the nucleophilic species.¹⁶ It has also been reported that

coordination to the diphosphane to a metal enhances the partial degradation process.¹⁷ A possible explanation to the fact that in both experiments is the diphosphane the partially degraded carborane ligand could be substitution of PPh₂ in the diphosphane by Me in the monophosphane, would lead to a less favorable nucleophilic attack over one of the boron atoms nearest to the carbon ones.

Scheme 2. i) [AuCl(tht)]; CH₂Cl₂; ii) [Au(tht)₂]OTf, CH₂Cl₂; iii) 1/2 [Au(tht)₂]OTf, CH₂Cl₂; iv) [Ag(OTf)(1,2-(PPh₂)₂-C₂B₁₀H₁₀)] or [AuCl(1,2-(PPh₂)₂-C₂B₁₀H₁₀)], EtOH/ Δ; v) 1,2-(PPh₂)₂-C₂B₁₀H₁₀, CH₂Cl₂; vi) PPh₃, CH₂Cl₂; vii) 1-PPh₂-2-Me-C₂B₁₀H₁₀, CH₂Cl₂; viii) 2 LiⁿBu, *ortho*-carborane, ix) 2 LiⁿBu, *para*-carborane

The I.R. spectra and ¹H NMR spectra of compounds **4** and **5** prove the presence of the carborane clusters, in addition the partial degradation of the carborane cages is confirmed by the presence of a broad signal at about -2 ppm in the ¹H NMR spectra, assigned to the bridging hydrogen atom in the open face of the *nido*-carborane. The ³¹P{¹H} NMR spectra consist on AX₂ (**4**) or AB₂ (**5**) systems which confirm the expected geometry, but the pattern of that corresponding to **4** is complicated by coupling to the silver ¹⁰⁷Ag and ¹⁰⁹Ag nuclei.

The crystal structure of compound **5** has been elucidated by X-ray diffraction studies (Figure 2). The gold atom displays a trigonal planar geometry with the gold center 0.12 Å

out of the plane formed by the three phosphorous atoms P1, P2 and P3. The major distortion is due to the chelate angle of the diphosphane [P-Au-P = 83.18(6)°].

The bonding distances and angles may be compared (Table 2) with different three coordinated species^{18,5s,5t,5v} as [Au(1,2-(PPh₂)₂-C₂B₁₀H₁₀)(PPh₃)]OTf or [Au(7,8-(PPh₂)₂-C₂B₉H₁₀)}(PR₃)] (PR₃ = monophosphane).

Complexes **1** and **2** contain a chloride and tht ligand, respectively which, upon reaction with carbanionic species (as RLi) of the former or through substitution of the tht ligand in the later, may lead to organometallic or metallorganic gold complexes (Scheme 1). Thus, substitution of tht in **2** by 1,2-(PPh₂)₂-C₂B₁₀H₁₀, leads to the formation of [Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)(1,2-(PPh₂)₂-C₂B₁₀H₁₀)]OTf (**6**), which is analogous to **5**, but contains two *closo*-carborane ligands, and thus is an ionic compound. Similar features are observed in the IR and NMR spectra of **5** and **6**, except for the absence of the signal at -2 ppm and the presence of the vibrations corresponding to the presence of the triflate group in the ¹H NMR and IR spectrum of **6**, respectively. The ³¹P{¹H} NMR spectrum of **6** consists on a AX₂ system.

The ³¹P{¹H} NMR spectrum of the reaction of **2** with PPh₃ consists on a AB system assigned to the expected complex **7** and two singlets at 62.4 ppm and 45.1 ppm, corresponding to the homoleptic species [Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂]OTf and [Au(PPh₃)₂]OTf, respectively. Equilibrium P^A-Au-P^B ↔ P^A-Au-P^A + P^B-Au-P^B in solution between mixed and homoleptic species are well known in gold chemistry.

Figure 2. ORTEP representation of compound **5**. Hydrogen atoms have been omitted for clarity.

Table 2. Bond lengths [Å] and angles [°] for [Au(7,8-(PPh₂)₂-C₂B₉H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)] (**5**) and other three coordinated gold complexes with diphosphanocarborane ligands.

As discussed above, complex [AuCl(1-PPh₂-2-Me-C₂B₁₀H₁₀)] **1** may react with carbanionic reagents as RLi. Such processes afford complexes [AuR(1-PPh₂-2-Me-C₂B₁₀H₁₀)]. We have chosen the *meta*- and *para*- isomers of carborane as R fragments. Thus, reaction of 1,*n*-(LiC)₂B₁₀H₁₀ (*n* = 2, 12) with **1** in molar ratio 1:2 affords the organometallic complexes [Au₂(μ-1,*n*-C₂B₁₀H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂] (**8**, *n* = 2; **9**, *n* = 12). The I.R. and ¹H NMR spectra confirm the presence of the carborane cluster. The ³¹P{¹H} NMR spectra of both complexes display one singlet at about 54 ppm. The crystal structure of **8** has been elucidated by X-ray diffraction studies (Figure 3). The gold centers display linear geometry. Gold distances and angles are in the range found for complexes [Au₂(μ-1,*n*-C₂B₁₀H₁₀)(PPh₃)₂] (*n* = 2, 7, 12; PR₃ = PPh₃ or PMe₃) which are shown in Table 3. No aurophilic contact has been found in **8** between the gold centers [Au⋯Au distance ca. 3.5 Å]. Comparison of the Au-Au distances in Table 3 indicates that complexes with PPh₃ or PMe₃ display no aurophilic interaction. So the use of the smaller PMe₃ monophosphane seems not to lead to the presence of aurophilic interaction. Aurophilic interactions have been found in complexes with diphosphane [7,8-(PPh₂)₂-C₂B₉H₁₀]⁻ and dithiolate [1,2-S₂-C₂B₁₀H₁₀]⁻² carborane ligands.¹⁹ So that maybe it is the carborane geometry that leads to such an orientation of the C-Au bonds that does not allow the two gold atoms to get closer each other.

*Carborane carbon atoms

Luminescence studies

The emission spectra of complexes **4** and **5** in the solid state at 298 K (Figure 4) exhibit one emission whose maximum appears at 397 nm for **4** and at 480 nm for **5**. At 77 K, compound **4** shows one band with a maximum at 450 nm. Two different emissions are observed for **5** at 77 K. Upon excitation at 320 nm the emission maximum appears at 526 nm. Excitation at lower energies leads to a weaker emission in the red region.

Figure 4. Normalized emission spectra of **4** and **5** at room temperature (left) and 77K (right)

Our previous results indicate that the free *nido*-diphosphane and three coordinated gold complexes $[M(7,8-(PR_2)_2C_2B_9H_{10})\{PR'_3\}]$ ($M = Au, Ag, Cu$; $R = Ph, ^iPr$) are luminescent $^{10s-10v}$ with lifetimes in the microsecond range ^{10t,10v} and aid in the assignation of the origin of the emissions.

The emission observed in the blue-yellow region resembles those of the free *nido*-diphosphane. They have been assigned to intraligand transitions (IL) modified upon coordination to the metal. The energy maximum for this IL band is lower for the gold complex (**5**), compared with the silver one (**4**). There is a shift to the red region upon coordination of the free diphosphane, compared with the emission of the free *nido*-diphosphane, and this shift follows the same trend reported for complexes $[M(7,8-(PR_2)_2C_2B_9H_{10})\{PR'_3\}]$ with other monophosphanes for which the influence of the metal in this IL band follows the pattern $Au > Ag$. The red emission observed for **5** at 77 K is also consistent with the low energy emissions observed for three-coordinate gold complexes with this diphosphane, which have been assigned to metal to ligand charge transfer (MLCT) transitions or a mixture of MLCT and intra-ligand charge transfer (ILCT) transitions.

We have also studied the luminescent characteristics of **8** and **9**, as different *ortho*-, *meta*-, and *para*-dinuclear gold derivatives of stoichiometry $[Au_2(\mu-1,n-C_2B_{10}H_{10})(PR_3)_2]$ ($n = 2, 7, 12$; $PR_3 = PPh_3, PMe_3$) are luminescent (Figure 5, Table 4).^{3g} We have found that **8** and **9** are not emissive in the solid state at room temperature. At 77 K, in the solid state, complex **8** displays two bands. Upon excitation at 280 nm, an emission at 480 nm is observed, whereas excitation at lower energies lead to a band centered at 580 nm. Compound **9** displays one band at 680 nm upon excitation at 360 nm. Dual emission, at similar energies has been

observed for organometallic dinuclear complexes of formula $[\text{Au}_2(\mu\text{-}1, n\text{-C}_2\text{B}_{10}\text{H}_{10})(\text{PR}_3)_2]$ (Table 4). The band at higher energy has been attributed to IL(carborane) transitions and the Stokes shift points to a fluorescent nature, and the one at lower energy to charge transfer transitions involving the gold centers in the reported examples, and the Stokes shift seems to point to a phosphorescent nature.

Table 3. Emission maxima (nm) for solid samples of complexes $[\text{M}(7,8\text{-}(\text{PR}_2)_2\text{C}_2\text{B}_x\text{H}_{10})\{\text{PR}'_3\}]^n$ [$x = 9, n = 0$; $x = 10, n = +1$; $\text{M} = \text{Au}, \text{Ag}$]

It is noticeable that **8** and **9**, both containing the carborane monophosphane are not emissive at room temperature. Quenching processes are difficult to predict. Objective facts when comparing $[\text{Au}_2(\mu\text{-}1,2\text{-C}_2\text{B}_{10}\text{H}_{10})(\text{PPh}_3)_2]$ and **8** are the more electron withdrawing nature of the carborane cluster, compared with the phenyl unit and the three dimensional aromatic nature of the carborane cluster. Although a concrete quenching mechanism is difficult to predict, it is possible to discuss the different behaviour of **8** and **9** at room temperature and 77K and the quenching of the IL emission at 77 K in **8** but not in **9** as follows. The rigidity imposed at 77K could explain the emissive behavior at this temperature, as quenching processes are in many cases less favorable at low temperatures and rigidity favors the emissive behavior. Nevertheless it is interesting to observe that the emission which is quenched in **9** both at room temperature and 77K is that assigned to IL (carborane) transition, but not that at lower energy, attributed to charge transfer processes

involving the gold center. It seems that, for **9** at high temperature quenching of the first excited singlet occurs. Upon cooling intersystem crossing is more favorable than direct decay to the ground state and phosphorescent charge transfer transitions lead to red emission. Changing the *para* isomer in **9** by the *ortho* isomer in **8** seems to make less favourable intersystem crossing and thus, both fluorescence and phosphorescence are observed in **8**.

Figure 5. Normalized emission spectra of **8** (dual emission) and **9** at 77 K.

Table 5. Emission maxima (nm) of organometallic gold complexes with carborane ligands. Excitation wavelength for the higher energy band is about 290 nm and about 400 nm for the lower energy band.

Pyrolysis and conversion to gold crystals

Two complexes have been selected for these studies, compound **1** (mononuclear) with 34.4 % of gold and 18.8 % boron content and compound **9** (dinuclear) with lower gold (32.3 %) but higher boron (26.6 %) content. Compounds **1** and **9** have been heated to 800 °C in air, whereas **1** was selected for the study after its deposition on Si or SiO₂ surfaces and dryness and heating to 800°C.

Pyrolysis of [AuCl(1-PPh₂-2-Me-C₂B₁₀H₁₀)] (**1**) and [Au₂(μ-1,n-C₂B₁₀H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂] (**9**)

Pyrolysis of the Au precursors **1** and **9** at 800 °C in air, results in a reddish-yellow solid that adheres well to the crucible. XRD patterns indicate the presence of pure cubic gold crystals. The typical strong reflexions for the (111), (200), (220) and (311) planes of metallic gold in a face-centered cubic lattice were observed as shown in Fig. 6¹⁰, for the pyrolytic product from **1**. Similar XRD pattern was observed for the product from thermolysis of **9**. SEM imaging shows, for both pyrolytic products, a sponge-like porous morphology²⁰. EDS analysis also confirmed that only pure Au is present. Consistent with the SEM observations TEM analysis confirms the porous gold comprises agglomerated crystals arranged in a random matrix akin to a 3D disordered gyroidal morphology. Porous metals have been recently employed for ultra-sensitive surface-enhanced Raman scattering (SERS) substrates²¹ and have unique properties such as low density, gas permeability and high surface area of high index crystal facets for catalysis, hydrogen storage and other applications. Preparative methods for metal foams to date most commonly involve dealloying of bimetallic Au_xAg_y.²²

Figure 6. XRD patterns of crystalline porous Au from direct pyrolysis of compound **1**. (Inset left) SEM image of the porous gold morphology, scale bar 5μm. (Inset right) TEM image: agglomerated crystals of the structure of the porous gold, scale bar 1.5μm.

Pyrolysis of [AuCl(1-PPh₂-2-Me-C₂B₁₀H₁₀)] (1) deposited on silicon or silica

Using precursor **1**, we successfully afforded complex geometrically shaped single Au crystals directly from pyrolysis of the previously deposited sample. The important gold content in **1** (36.21%) leads to demixed phases and mobile agglomeration. This demixing process results from the interaction of inert Au NPs within a decomposing organic phase that undergoes carbonization. Prior to solidification as a carbon, the separated Au NPs migrate and agglomerate to crystallize as larger single crystals. This association process is similarly found in Au NPs on PMMA or PS thin films²³ and has been described by Avrami kinetics for solid species within liquid polymer films, and by Ostwald ripening in thermally driven solid state processes. In the present case, agglomeration and growth of a larger single crystal from the nanoparticles is observed to occur until the surrounding carbonaceous material solidifies. This solidification is the reason for the variety in sizes and geometries of the resulting crystals; their shape, dispersion and size depend on the local density of building block NPs of Au formed through the initial decomposition of the gold containing complexes.

The initially formed gold nanoparticulate clusters ripen to microcrystals with defined shapes. The growth of gold microcrystals eventually stops when triangular plates are formed. In some cases these plates ripen to full tetrahedra. This happens in some cases, when sufficient gold source is present in the surrounding area (depending on the density of other growing crystal in the vicinity using the Au source within the deposit). Structural variants related to the cubic structure are mainly represented, followed by octahedral fully formed crystals.

The gold comes from the complex and the decomposing carborane precursor results in a carbon residue that is removed after the end of the pyrolytic process. Figure 7 illustrates this process.

Deposition on Si and pyrolysis [Fig. 7a] leads to spherical crystals which develop faceting only if enough atomic source is available. As a high density of nucleated crystals is formed, many remain non-faceted. At the earlier stages of the pyrolysis of the dichlorometane solutions of **1** deposited on silica (Fig. 7b1), the crystals are found on the surface of a roughening carbon residue and subsequent time allows for shape development and diameter increase [Fig. 7b (2-4)].

Without relying on ligands or shape selective surfactants (the organic matrix decomposes and thus does not fulfill this function in the present case) a random but uniform surface coverage of individual crystals (Fig. 7a,b) shows the variety of crystal shapes

possible through coarsening of NPs formed by cleavage, agglomeration and ripening of metal atoms. Compositional analysis using EDX mapping in Fig. 7c confirms that the polyhedral crystals are phase pure.

Figure 8 shows that the early stage crystals formed by pyrolysis of dichloromethane solutions of **9** deposited on SiO₂ are surrounded by a thin carbon coating. Larger crystals that are faceted also are likely to contain a very thin layer, and quantitative EDS shows that some remnant carbon is likely to stem from underlying carbon as the measurement also detects oxygen from the underlying substrate. Typically, the fully formed crystals post pyrolysis are free from carbon coatings.

Figure 7. Various stage of the crystal growth where small low density crystals eventually becomes a higher density of larger crystals with further pyrolysis followed by SEM images of precursor **1** deposited on Si (a) and SiO₂ (b1-b4) after pyrolysis. (c) The EDX mapping confirms that Au content for the particles and some regions of the surrounding precursor where the Au source has not agglomerated to the growing crystals.

In terms of their formation, phase separation of the metal from the organic portion of the precursor is expected, as has been found in asymmetric polymer-particle mixtures²⁴ for large particle-to-monomer size ratios. An entropically driven surface phase transition has

been observed²⁵ for low-Mw simpler polymer-particle thin films, resulting in the expulsion and layering of NPs along the solid substrate. Au association, observed in the bulk above a threshold temperature,²⁶ forms into a ripening phase that is bound to the surface and fed from the Au content within the surrounding matrix, within and on a carbonaceous material during pyrolysis. Low-Mw thin composite films have been shown to form a diffuse layer of NPs at the substrate interface after spin coating which failed to be redispersed by subsequent thermal annealing. A phase separation and crystallization, where NPs form due to the chemical decomposition, allows crystals eventually grow due to the physical decomposition. The decomposition follows expected pathways, including carbonization and release of Au metals, similar to what we demonstrated using other forms of Au-containing phosphazene structures. There is no formal relationship between the nanostructures and the crystal structure of the compound. The nanostructures form from migration and crystallization of nanoparticles that are formed from the release of metal centers during decomposition, which is outlined in the manuscript. Further work will be required to determine the kinetics and coarsening/crystallization of metal crystal from these types of precursors.

Figure 8. Studies of the pyrolysis of solutions in dichloromethane of **1** deposited on SiO₂. (a) Early stage Au crystal prior to full facet development coated with a remnant carbon

overlayer (see inset). Scale bar = 100 nm. (b) EDS map analysis of elemental (i) C (white), (ii) Si substrate, and (ii) Au (yellow). Scale bar = 1 μ m

CONCLUSIONS

Gold and silver complexes have been synthesized with the 1-PPh₂-2-Me-C₂B₁₀H₁₀ monophosphane. Complexes [AuCl(1-PPh₂-2-Me-C₂B₁₀H₁₀)] (**1**) and [Au(1-PPh₂-2-Me-C₂B₁₀H₁₀)(tht)]OTf (**2**) are good starting products in the synthesis of metallorganic or organometallic derivatives.

Complexes [M(7,8-(PPh₂)₂-C₂B₉H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)] [M = Ag (**4**), Au (**5**)] and [Au₂(μ -1,*n*-C₂B₁₀H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂] [*n* = 1 (**8**), 12 (**9**)] are luminescent. Dual emission has been observed for **5** and **8**. The emissive behaviour is attributed to the metal center and the *nido*-carborane diphosphane in the three coordinated compounds, or to the carborane cluster and the gold centers in the dinuclear complexes. Derivatives [M(7,8-(PPh₂)₂-C₂B₉H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)] [M = Ag (**4**), Au (**5**)] follow the pattern observed for similar complexes with other monophosphanes. The influence of the metal in the emission energy of the band at higher energy follows the order Au > Ag. Complexes [Au₂(μ -1,*n*-C₂B₁₀H₁₀)(1-PPh₂-2-Me-C₂B₁₀H₁₀)₂] [*n* = 1 (**8**), 12 (**9**)] exhibit differences with the homologous containing other monophosphanes. They are not luminescent at room temperature and for compound **9** only the emission at lower energy is observed. Dual emissions have been observed for **8** at 77K which are observed for the analogous complexes with other monophosphanes both at room temperature and 77K. The presence of the electron withdrawing *closo*-carborane-monophosphane leads to the quenching of both emissions at room temperature for **8** and **9**, and to the emission at higher energy for **9** at 77 K. It seems that in **9** intersystem crossing is the most important process leading only to the phosphorescent emission.

Compounds **1** and **9** are useful solid-state precursors for forming porous metals via agglomeration (but of individual single crystals) or shaped Au microcrystals depending on the pyrolysis conditions. As observed for other metals (noble and transition),^{11,19,27} pyrolysis on Si or SiO₂ wafers produces crystals that include nanoparticle formation, mobility through the composite and ripening crystallization into defined shapes and with a relatively uniform spatial distribution when pyrolyzed on substrates. The decomposition process and resulting mechanism is inherently linked to the structure of the compounds. The use of molecular Au-carborane-monophosphane precursors leads to the formation of Au phase pure products and

the formation of BPO_4 , which is a product of the pyrolysis of $\{[\text{NP}(\{\text{OCH}_2\}_2\text{C}_2\text{B}_{10}\text{H}_{10})]_{0.5}[\text{NP}(\{\text{OCH}_2\}_2\text{C}_2\text{B}_9\text{H}_{10}\bullet\text{NBu}_4)]_{0.5}\}_n$ has not been detected.

ACKNOWLEDGMENT. We thank the Ministerio de Economía y Competitividad-FEDER (No. CTQ2010-20500-C02-01) and DGA-FSE (E77) and FONDECYT project 1120179.
