Temporal evolution with gestational age dependencies

Figure S1 presents a visualisation of the changing temporal trajectories with increasing GA specific to these 6 features. For example, for infants born at 24 weeks of gestation, there is a large increase in δ -band spectral power (approximately $700 \mu V^2$) over the first 60 hours of life. For infants born at 32 weeks of gestation however, there is a small decrease in the spectral power (approximately $50 \mu V^2$) over the same time period.

Figure S1. Trajectories of the time fixed-effect (postnatal age, as solid lines) plotted at selected gestational ages. The dashed line represents a baseline at 6 hours PNA.

Medication and qEEG: multiple linear regression

Estimates of the independent variable representing medication therapies: surfactant in Table S1 and fentanyl in Table S2. GA is also included as an independent variable with the time-averaged qEEG feature as the dependent variable.

Table S1. Coefficient estimates for surfactant replacement therapy.

Feature type				Regression coefficient
