19 expression

## 20 Abstract

21 Nisin A is a potent antimicrobial with potential as an alternative to traditional antibiotics, and a  
22 number of genetically modified variants have been created that target clinically relevant  
23 pathogens. In addition to antimicrobial activity, nisin auto-regulates its own production via a  
24 signal transduction pathway, a property that has been exploited in a protein expression system  
25 termed the Nisin Controlled Gene Expression (NICE) system. Although NICE has become one  
26 of the most popular protein expression systems, one drawback is that the inducer peptide, nisin  
27 A, also has inhibitory activity. It has already been demonstrated that the N-terminal region of  
28 nisin A contributes to antimicrobial activity and signal transduction properties, therefore, we  
29 conducted bioengineering of nisin at positions Pro9 and Gly10 within ring B to produce a bank  
30 of variants that could potentially be used as alternative induction peptides. One variant,  
31 designated nisin M, has threonines at positions 9 and 10 and retains induction capacity  
32 comparable to the wild type nisin A, while most of the antimicrobial activity is abolished.  
33 Further analysis confirmed that nisin M produces a mix of peptides as a result of different  
34 degrees of dehydration of the two threonines. We show that nisin M exhibits potential as a more  
35 suitable alternative to nisin A for the expression of proteins that may be difficult to express, or to  
36 produce proteins in strains that are sensitive to wild type nisin. Moreover, it may address the  
37 increasing demand by industry for optimization of peptide fermentations to increase yields or  
38 their production rate.

39

40

41

42

43 Importance

44 This study describes the generation of a nisin variant with superior characteristics for use in the  
45 NICE protein expression system. The variant, termed nisin M, retains an induction capacity  
46 comparable to the wild type nisin A but exhibits significantly reduced antimicrobial activity and  
47 can therefore be used at concentrations that are normally toxic to the expression host.

61

62 Introduction

63 Producing high quantities of proteins of biotechnological and pharmaceutical value from their  
64 natural sources can have economic challenges. Although *Escherichia coli* has been the dominant  
65 player in the production of recombinant proteins for decades, several issues including the  
66 presence of endotoxin or lipopolysaccharide requires expensive and often problematic  
67 downstream purification processes (1). The lactic acid bacteria (LAB) *Lactococcus lactis* has  
68 gained importance as a host for heterologous protein expression due to its well understood  
69 genetics and metabolism, generally regarded as safe (GRAS) status, as well as the availability of  
70 a wide range of genetic tools. Indeed, a major advance with regards to protein expression in *L.*  
71 *lactis* was the discovery and use of gene expression systems based on a number of inducible  
72 promoters. These include promoters that respond to the environment such as P170, which is  
73 upregulated at low pH (2) and zinc-based systems that respond to zinc availability (3). One of  
74 the best known and most widely employed expression systems is the nisin-inducible controlled  
75 gene expression (NICE) system (4, 5) which stems from the nisin biosynthetic operon  
76 (*nisABTCIPRKFE*) found in some *L. lactis* strains (6). Nisin is a 34 amino acid peptide and is  
77 the most extensively studied bacteriocin (ribosomally synthesized, antimicrobial peptides  
78 produced by bacteria) (7, 8). It targets a wide range of Gram-positive bacteria, including food  
79 pathogens such as *Listeria monocytogenes*, *Staphylococcus aureus*, *Bacillus cereus* and clostridia  
80 (9, 10). Nisin induces its own biosynthesis via a two-component signal transduction pathway  
81 NisRK (6) and has led to the development and application of a food grade expression system  
82 using *L. lactis* as the host (11). The NICE system encompasses both regulatory elements of the  
83 nisin operon, *PnisA*, the nisin-inducible promoter (cloned into several expression vectors) and  
84 *nisRK*, the two component histidine kinase response regulator system (harboured by compatible

85 plasmids or inserted on the chromosome of a suitable host strain). The system is ‘switched on’  
86 by the addition of nisin in the nanomolar range which activates the receptor NisK. NisK activates  
87 NisR by phosphorylation and the activated NisR induces expression at the nisin A promoter (4).  
88 The NICE system has been extensively used to produce proteins in *L. lactis*, such as  
89 bacteriophage lysins and metalloendopeptidases to demonstrate their potential in dairy  
90 fermentations (12, 13). Moreover, NICE can, under certain conditions and with some  
91 modifications to the system components, also be used in other species of LAB and in other  
92 Gram-positive bacteria (11, 14). Its numerous advantages include ease of use, exquisitely  
93 controlled and efficiently induced expression and amenability to large-scale production  
94 processes. As an example, nisin induced fermentations of the antimicrobial lysostaphin have  
95 been carried out and even identified areas of the NICE system that need improvement (5).  
96 However, for industrial applications, nisin addition remains costly (15). Another drawback of the  
97 system is that the inducing peptide is also toxic due to its potent antimicrobial activity.  
98 Therefore, a nisin peptide that retains its induction capacity whilst having little to no  
99 antimicrobial activity would be highly desirable. The gene-encoded nature of the nisin peptide  
100 makes genetic engineering to develop certain characteristics of the molecule an attractive and  
101 feasible option. Although the bioengineering of nisin commenced over three decades ago, the  
102 majority of studies have largely focused on identifying nisin variants with enhanced  
103 antimicrobial activity or an extended-antimicrobial spectrum (10, 16, 17). The importance of the  
104 N-terminus rings A and B with respect to induction has been highlighted on a number of  
105 occasions (6, 16, 18). These studies involved either combinatorial saturation mutagenesis of  
106 rings A and B (18) or the application of alanine scanning approaches to assess the antimicrobial  
107 activity and induction properties of various nisin derivatives (16).

108 In this study, we carried out a more comprehensive bioengineering approach and created banks  
109 of nisin derivatives that have been randomized at positions 9 (P9X) and 10 (G10X) individually  
110 and in combination (P9XG10X) and assessed them for antimicrobial activity in conjunction with  
111 their ability to induce the nisin promoter using GFP and  $\beta$ -galactosidase reporter systems.

## 127 Results

128 Creation and screening nisin derivatives for antimicrobial activity and induction capacity.

129 Previous studies utilising site-directed and alanine scanning mutagenesis of nisin have revealed  
130 that the N-terminal ring structures are an important region required to activate NisRK (16, 18). In  
131 particular, mutagenesis of ring B has been shown to modulate antimicrobial and induction  
132 activity. We selected this location as a suitable target for the generation of variants to screen for  
133 our desired activities. In order to fully exploit the potential of the nisin ring B we undertook a  
134 complete randomisation of the two amino acids in Pro9 and Gly10, both alone (P9X, G10X) and  
135 in combination (P9XG10X) using NNK scanning of both codons in the nisin A structural gene  
136 (*nisA*) as previously described (7). A bank consisting of 1,452 individual variants created in *L.*  
137 *lactis* NZ9800 pCI372*nisA* (pDF05) were screened for antimicrobial activity using deferred  
138 antagonism agar diffusion assays and their ability to induce the nisin promoter, *PnisA* fused to a  
139 *gfp* reporter gene. The impact of mutations targeting position nine (proline) on antimicrobial  
140 activity was assessed using an overlay assay and resulted in zones ranging from those  
141 comparable to the wild type control to those devoid of any observable activity. Analysis of  
142 colonies using mass spectrometry and/or DNA sequencing identified 12 different amino acid  
143 substitutions corresponding to P9H, P9E, P9S, P9T, P9N, P9A, P9M, P9I, P9V P9L, P9W, and  
144 P9F (Figure 1A). Substituting P9 with an alanine (P9A) had no impact on either antimicrobial  
145 activity or induction capacity. A number of variants (P9H, P9E, P9W and P9F) displayed a loss  
146 of both properties. Several others (P9M, P9L, P9N, P9V and P9I) displayed a significant  
147 reduction in antimicrobial activity (between 50-65% of wild type) as well as a reduced ability to  
148 induce the *gfp* reporter. Notably, P9T and P9S exhibited a slight reduction in antimicrobial

149 activity (70-75%) but retained 100% and 75% induction capacity respectively compared to the  
150 wild type control (Figure 1A), which was in agreement with previous studies (16, 18). It is  
151 significant that replacement of P9 with either threonine or serine introduces hydroxylated  
152 residues which could act as substrates for the lanthionine modification machinery. Indeed,  
153 colony mass spectrometry (CMS) of the P9T and P9S producers revealed the presence of masses  
154 corresponding to the presence of both unmodified (threonine or serine) and modified residues  
155 (dehydrobutyrine (Dhb) or dehydroalanine (Dha)) (Table1).

156 Analysis of 144 variants where position 10 (glycine) was targeted, revealed that the majority of  
157 clones exhibited either wild type activity or displayed a complete loss of both antimicrobial  
158 activity and induction capacity. Mass Spectrometry (MS) and DNA sequencing determined that  
159 almost all of the active variants had retained the original glycine at position 10 (wild type), but  
160 we also detected variants corresponding to G10T and G10S (Figure 1B). Here too, CMS  
161 identified a mixture of both modified and non-modified residues in the case of G10S (i.e. G10S  
162 and G10Dha) but this was not observed when threonine was present at position 10. A variant that  
163 displayed little reduction in activity (>50%) had an alanine (G10A) substitution (Figure 1B). A  
164 selection of variants that lacked both antimicrobial activity and induction capacity were  
165 subjected to DNA sequencing analysis, which identified substitutions corresponding to G10F,  
166 G10W and G10L. The inability to detect as wide a range of active variants at this position may  
167 arise from the fact that several variants in this position (including G10D, G10N, G10H, G10R,  
168 G10L and G10P) have been linked with the loss of threonine dehydration at position 8, meaning  
169 that ring B does not undergo cyclization (18).

170 We then set out to vary both residues 9 and 10 simultaneously. As expected, screening of the  
171 doubly randomized P9XG10X bank revealed far fewer bioactive variants (approx. 5.6% of the

total) of which the majority were wild type (38/64). The remainder exhibited varying degrees of antimicrobial activity ranging from 10-50% with a concomitant loss in induction capacity (data not shown). However, one clone was conspicuous in that despite its apparent lack of antimicrobial activity, it retained an induction capability comparable to the wild type nisin A (Figure 2A). DNA sequencing analysis revealed a variant corresponding to P9T/G10T (both residues replaced with a threonine, Fig 2B). Furthermore, CMS revealed the presence of masses corresponding to the doubly-modified TT peptide (Dhb9Dhb10) but also species with one modified residue to Dhb and a mass close to a peptide with no modified threonine residues (Figure 2A; Table 1). Purification of the derivative P9T/G10T, we termed nisin M, was carried out with our standard nisin purification protocol and subsequent high-performance liquid chromatography (HPLC) evaluation revealed the presence of two major peaks (data not shown). Mass spectrometry analysis of these fractions revealed the presence of one peptide of 3365 Da (consistent with the presence of two Dhb's) and a second peptide of 3383 Da (consistent with a peptide with one threonine and one Dhb). Additionally, a mass in close agreement to a non-modified peptide with threonines in both positions was also observed (data not shown).

187

188 Minimum inhibitory concentration (MIC) of nisin M

Following HPLC and freeze-drying of combined fractions to obtain pure peptides, MIC assays were carried out using equimolar concentrations of nisin A and nisin M against a range of Gram positive targets including genera into which the NICE system has been previously introduced (Table 2). The MIC was determined to be the lowest concentration of peptide that resulted in the absence of visible growth of the target strain after 16 hours under the appropriate growth conditions. We established that the MIC of nisin M against a standard laboratory indicator *L.*

195 *lactis* HP was  $2.5 \mu\text{g mL}^{-1}$ , reflecting a 16-fold increase in MIC compared to wild type nisin A  
196 ( $0.156 \mu\text{g mL}^{-1}$ ). Nisin M displayed a similar decrease in potency against the *L. lactis* NZ9000  
197 *gfp* reporter strain and its isogenic equivalent *L. lactis* NZ9000 (Table 2). Several lactobacilli  
198 have been used as hosts of the NICE system including *Lactobacillus plantarum*, *Lactobacillus*  
199 *helveticus* and *Lactobacillus brevis* (14, 19). When *Lb. plantarum* UCC16 and *Lb. brevis* SA-  
200 C12 were assessed, an MIC of  $>2.5 \mu\text{g mL}^{-1}$  and  $1.25 \mu\text{g mL}^{-1}$  was observed, demonstrating a  
201  $>4$ -fold and 16-fold decrease in antimicrobial activity for nisin M respectively in comparison to  
202 wild type peptide. (Table 2).

203

204 Induction capacity of nisin A and nisin M at  $10 \text{ ng mL}^{-1}$

205 Determination of the induction capacity of nisin A and nisin M at a concentration of  $10 \text{ ng mL}^{-1}$   
206 was performed using two reporter systems, by way of measurement of GFP and  $\beta$ -galactosidase  
207 production. There was no statistical difference in the dynamics of RLU detection when the GFP  
208 reporter strain was induced with nisin A and nisin M ( $P > .05$ ) (Figure 3A). Similarly, induction  
209 of the *βgal*<sup>+</sup> reporter strain also revealed no significant difference between nisin A and nisin M  
210 at equivalent concentrations ( $10 \text{ ng mL}^{-1}$ ) ( $P > .05$ ) (Figure 3B). Moreover, the rate of expression,  
211 and therefore the rate of induction was identical for both nisin A and nisin M under the  
212 conditions tested in both GFP and  $\beta$ -galactosidase assays.

213

214 Induction capacity and effect on growth of nisin reporter strain at higher induction  
215 concentrations

216 Next, we employed 50 ng mL<sup>-1</sup>, 100 ng mL<sup>-1</sup> and 300 ng mL<sup>-1</sup> of peptide to determine the effect  
217 of higher concentrations of nisin A and M on both protein expression and on growth of the  
218 expression host. Fluorescence (RLU) was measured to determine GFP expression and  
219 absorbance readings at OD<sub>595nm</sub> were taken to observe growth of induced strains. For each of  
220 these higher concentrations a significant difference between the level of induction by nisin A and  
221 nisin M ( $P < .0005$ ) was noted (Fig. 4A-C). Interestingly, the highest RLU reading attained was  
222 from cells induced with nisin M at a final concentration of 50 ng mL<sup>-1</sup>. At this concentration  
223 induction continued for the course of the experiment (18 hrs), whereas at 100 ng mL<sup>-1</sup> and 300 ng  
224 mL<sup>-1</sup> induction reached maximum and decreased after 10-12 hours. Notably, there was no delay  
225 in the rate of GFP expression following induction with nisin M at 50 ng mL<sup>-1</sup> and 100 ng mL<sup>-1</sup>  
226 (Figure 4A-B) compared to 10 ng mL<sup>-1</sup> (Figure 3A), where fluorescence intensifies at  
227 approximately 6 hours post induction for all experiments; meanwhile, there was a minor delay of  
228 30 minutes in expression with induction at 300 ng mL<sup>-1</sup> (Figure 4C).

229 When the effects on growth were analysed, no significant impact on the growth of the GFP  
230 reporter strain was observed following induction with nisin M at 50 ng mL<sup>-1</sup> ( $P > .05$ ), 100 ng  
231 mL<sup>-1</sup> ( $P > .05$ ) and 300 ng mL<sup>-1</sup> ( $P > .05$ ). The OD<sub>595</sub> of both non-induced cells and cells induced  
232 with nisin M increased approximately 5 hours post induction. However, induction with nisin A at  
233 the same concentrations resulted in a significant lag-time in growth. An increase in OD<sub>595</sub> was  
234 not observed until 7.5, 8 and 10 hours post induction at 50 ng mL<sup>-1</sup> ( $P < .05$  for comparison of  
235 nisin M to WT,  $P < .0005$  for comparison of WT to uninduced samples), 100 ng mL<sup>-1</sup> ( $P < .0005$ )  
236 and 300 ng mL<sup>-1</sup> ( $P < .0005$ ), respectively. It is worth noting that although growth was observed  
237 by samples at these times following induction with WT nisin, there was no fluorescence detected  
238 from the same samples until 12, 16 and 18 hours, respectively (Figure 4A-C & 5A-C).

239

240

241 Discussion

242 Any new technological advancements to improve the production of protein biopharmaceuticals  
243 and industrial enzymes by microorganisms is highly desirable. Potential methods to optimize the  
244 efficiency of an inducible gene expression system may involve adjustment of inducer dosage  
245 and/or the timing of inducer addition. The Gram-positive NICE system is somewhat unusual in  
246 that the inducer peptide also has the capacity to kill the expression host, and thus induction and  
247 killing capacity must be balanced. The generation of a nisin derivative that retained its induction  
248 properties but with reduced antimicrobial properties would represent a significant improvement  
249 to the NICE system that could be applied to more sensitive strains.

250 Previous work, where the focus has been on the nisin peptide itself, involved randomised  
251 mutagenesis of rings A and B (18) and described mutants that retained considerable auto-  
252 induction abilities but with lower antimicrobial properties (and vice- versa). Similarly, Ge and  
253 co-workers (2016) applied a complete alanine scanning mutagenesis approach and reported that  
254 the N-terminal ring structures (ring A and ring B) in nisin were involved in activating NisK to  
255 act as an inducing molecule (16). In this study we focused our attention on ring B with a more  
256 systematic mutagenesis approach to identify novel derivatives with altered activity/induction  
257 properties. This proved to be successful in that we identified a nisin variant that retains induction  
258 capacity that is comparable to the wild type peptide but exhibits significantly less antimicrobial  
259 activity.

260 Notably, another lantibiotic, subtilin is structurally closely related to nisin and contains the same  
261 lanthionine ring structure but does not induce *PnisA*. Indeed, in the study by Steiß, Korn, Kötter  
262 and Entian (2015) the failure of subtilin to induce the histidine kinase NisK was shown to mostly  
263 depend on the presence of an N-terminal tryptophan, as its replacement with the aliphatic amino  
264 acid residues isoleucine, leucine, and valine led to activation of NisK (20). This suggests further  
265 bioengineering at position 1 and indeed other amino acid locations in the nisin M background  
266 could potentially enhance induction and reduce antimicrobial activity even further.

267 Although this study highlighted ring B of nisin as a critical region in our quest to separate  
268 antimicrobial activity from induction/pheromone activity, more residue positions could and  
269 should be targeted. Studies with the natural variant nisin Z have revealed that derivatives  
270 corresponding to T2S and M17W exhibited an 11-fold and 2-fold increase in induction capacity  
271 relative to the parent peptide, respectively, while derivatives S5T and S3T had significantly  
272 reduced induction capacity (7).

273 A computational approach evaluating the antimicrobial activity, induction capacity, production  
274 levels and immunity/sensor kinase components of natural and bioengineered nisin derivatives  
275 could provide a blueprint for the design of more efficient peptide inducers. For example, the  
276 ability of nisin P, A and H to activate *PnisA* fused to a *gfp* reporter was assessed and found to  
277 differ (21). The promoter was more sensitive to nisin A ( $1 \text{ ng mL}^{-1}$  –  $1 \text{ } \mu\text{g mL}^{-1}$ ) than nisin H ( $10$   
278  $\text{ng mL}^{-1}$  –  $1 \text{ } \mu\text{g mL}^{-1}$ ) and nisin P ( $100 \text{ ng mL}^{-1}$  –  $10 \text{ } \mu\text{g mL}^{-1}$ ). Higher concentrations of nisin P  
279 were required to activate the promotor, but it continued to induce promoter activity at higher  
280 concentrations ( $10 \text{ } \mu\text{g mL}^{-1}$ ) whereas nisin A and H were capable of inducing the promoter only  
281 up to  $1 \text{ } \mu\text{g mL}^{-1}$  concentrations of peptides. The ability to use higher concentrations of nisin P is  
282 most likely due to its decreased antimicrobial activity as compared with nisin A and nisin H.

283 While this might advocate for the use of nisin P as an alternative inducer to nisin A, the peptide  
284 does not induce at the lower and commonly used inducing concentration ( $10 \text{ ng mL}^{-1}$ ). Notably,  
285 the nisin M mutant generated in this study induces at both low and high concentrations. While  
286 no significant difference in growth of the induced strain compared to the un-induced control was  
287 observed, even at the maximum concentration applied ( $300 \text{ ng mL}^{-1}$ ), further evaluation with  
288 even higher concentrations of nisin M are necessary and with a variety of expression host strains.  
289 However, the practicality of using such high concentrations in terms of industrial applications  
290 would need to be considered, given that cell free supernatant from a nisin M producer would be  
291 the most likely option for induction (rather than expensive purified nisin peptides); though a  
292 fermentate analogous to nisaplin (2.5% nisin A) would enable a range of concentrations to be  
293 applied irrespective of the sensitivity of host strains (e.g. induction levels above  $10 \text{ ng mL}^{-1}$  nisin  
294 A results in inhibitory effects on the expression strain *L. lactis* NZ9000) (22).

295 Additionally, the natural variant nisin Q also displays similar antimicrobial capabilities to that of  
296 nisin A but differs in its ability to induce the *nisA* promoter (23). Directed mutagenesis and  
297 analysis of the four amino acids which differ between nisin A and nisin Q (A15V, M21L, H27N,  
298 I30V) may help us to more completely understand the pheromone activity of nisin. Remarkably,  
299 in the study by Ge and co-workers the derivatives L16D, L16A, L16H, L16V, M21A, M21D,  
300 and M21N all exhibited enhanced induction properties when assessed by  $\beta$ -Galactosidase assays,  
301 with L16D being particularly notable given it also displays a significant reduction in  
302 antimicrobial activity (16). Other regions of nisin subjected to bioengineering approaches and  
303 shown to impact on induction activity include the C-terminus and in particular serine and  
304 isoleucine at positions 29 and 30, respectively (24). Although the specifics of the interaction  
305 between the nisin peptide and NisK have yet to be fully elucidated, a recent study has provided

306 some insight through mutational analysis of NisK. Mutagenesis of conserved residues in the  
307 extracellular region of NisK revealed that several hydrophobic residues including two aromatic  
308 residues (Tyr113 and Phe133) are crucial for NisK in sensing nisin and regulating nisin  
309 biosynthesis (25).

310 Elimination of the antimicrobial activity of nisin is a priority when aiming to improve the nisin  
311 peptide in terms of its suitability as a peptide inducer, such as in the NICE system. For example,  
312 Reunanen & Saris (2003) developed a method for the quantification of nisin in food samples,  
313 through the construction of a non-nisin producing *L. lactis* strain (LAC240), with a plasmid  
314 containing a *gfp* gene under the control of the *nisF* promoter and the constituent genes of the  
315 nisin two-component regulatory system, *nisRK*. It was reported that upon the addition of nisin  
316 peptide concentrations greater than 20 ng mL<sup>-1</sup>, the LAC240 cells became stressed resulting in a  
317 reduction in the quantity of GFP produced and the signal reached the background level when the  
318 concentration of nisin was approximately 60 ng mL<sup>-1</sup> (26). Moreover, in a study that aimed to  
319 improve the response of *L. lactis* to freezing damage through expression of an antifreeze peptide  
320 (SF-P), the recombinant strain *L. lactis* NZ3900 SF-P was incubated with different  
321 concentrations of nisin (25, 50, or 100 ng mL<sup>-1</sup>) and at various pH and growth temperature  
322 values (27). Notably, maximal expression was observed at 25 ng mL<sup>-1</sup>, with a much lower level  
323 of expression at 50 ng mL<sup>-1</sup> and virtually no expression at 100 ng mL<sup>-1</sup>, most likely due to the  
324 inhibitory effects of nisin A, though pH and temperature values were also a factor (27). In  
325 another study that sought to optimize the NICE system for the expression of lysostaphin for both  
326 laboratory (1 L) and industrial-scale (3000 L) applications and at high cell densities, the authors  
327 noted that the addition of too much nisin was detrimental for product formation. Notably, when  
328 the culture was induced at higher cell densities, 160 mg L<sup>-1</sup> lysostaphin was formed with 20 ng

329 mL<sup>-1</sup> nisin and 220 mg L<sup>-1</sup> lysostaphin was produced when 40 ng mL<sup>-1</sup> nisin was used for  
330 induction, indicative of a clear correlation between the cell density at induction and the amount  
331 of nisin that is needed for maximal induction (5). While this group reported that maximum  
332 protein yield in the NICE system is achieved by induction carried out at a cell density of OD<sub>600</sub> =  
333 5 with a final concentration of 40 ng mL<sup>-1</sup> of nisin, we suggest that Nisin M provides for a  
334 greater flexibility with respect to inducer concentration by virtue of the attenuated antimicrobial  
335 activity of the peptides and the application of high concentrations of inducer peptide is not now a  
336 limiting factor.

337 To date, a multitude of peptides, enzymes and vaccines of clinical and biotechnological interest  
338 have been overexpressed using nisin, including the anti-bacterial protein lysostaphin (5), a  
339 haemagglutinin of the H5N1 influenza virus (28) and Rotavirus VP6 Protein (29), to name but a  
340 few. Though several improvements have been made to the NICE system, further improvements  
341 are possible. For example, streamlined-genome mutants of *L. lactis* NZ9000 were generated by  
342 deletion of four large nonessential DNA regions accounting for 2.83% of the genome and  
343 evaluated as microbial cell factories for recombinant protein production. Indeed, following nisin  
344 induction, not only was the transcriptional efficiency improved but also the production levels of  
345 the expressed reporters were approximately three to fourfold enhanced compared with the wild  
346 strain (30). Additionally, expression from the  $\Delta lacF$  host-strain *L. lactis* NZ3900 (a strain unable  
347 to utilize lactose), enabled food-grade, lactose-based plasmid selection and induction (31) whilst  
348 deletion of a specific proteinase gene (NZ9000  $\Delta htrA$ ) led to increased stability of heterologous-  
349 secreted proteins (32).

350 While the aforementioned studies focused on improving the host strain for expression of  
351 proteins, this study focuses on potential improvements that can be made to the inducing peptide

352 via mutagenesis of ring B, which has already been reported as playing an important role in  
353 induction capacity (16, 18). This study has demonstrated that a nisin A variant with  
354 modifications to ring B retained comparable induction capacity to the wild type nisin A peptide  
355 yet exhibited less inhibitory effects on the growth of the strain *L. lactis* NZ9000 when applied at  
356 concentrations as high as 300 ng mL<sup>-1</sup> (0.09 µM). It was also determined this combination has  
357 between >4 and >16 fold less activity against various genera and species of bacteria into which  
358 the NICE system has been introduced, therefore supporting the claim that nisin M exhibits  
359 potential as a suitable alternative to nisin A for use in the NICE system.

360 This study confirms that random mutagenesis experiments continue to be beneficial with a view  
361 to enhancing the functional properties of the nisin peptide for specific applications and provide  
362 novel nisin variants that exhibit potential for future applications in the pharmaceutical,  
363 biotechnological and industrial fields.

375

376 Materials and Methods:

377 Bacterial strains and plasmids

378 Bacterial strains and plasmids used in this study are listed in Table 3.

379 Creation and analysis of a bank of nisin A ring-B derivatives

380 Mutagenesis of the *nisA* gene was carried out as described previously (7). Briefly, saturation381 mutagenesis was carried out using pDF05 (pCI372-*nisA*) as template and using oligonucleotides

382 as listed in (Table 4) containing an NNK codon in place of each native codon. PCR amplification

383 was performed in a total volume of 50  $\mu$ L with 0.5 ng of target DNA (pCI372-*nisA*), 1 unit

384 Phusion High-Fidelity DNA polymerase (Finnzymes, Finland), 1 mM dNTPs and 500 ng each of

385 the appropriate forward and reverse oligonucleotides. The reaction was pre-heated at 98°C for

386 2 min, and then incubated for 29 cycles at 98°C for 30 s, 55°C for 15 s and 72°C for 3 min 30 s,

387 and then finished by incubating at 72°C for 3 min 30 s. Amplified products were treated with

388 DpnI (Stratagene) for 60 min at 37°C to digest template DNA and purified using the QIAquick

389 PCR purification kit. Following transformation of *E. coli* Top 10 cells plasmid DNA was isolated

390 and sequenced using primers pCI372FOR and pCI372REV (Table 4) to verify that mutagenesis

391 had taken place. The purified products were subsequently introduced by electroporation into the

392 strain *L. lactis* NZ9800 which has all the genes necessary for nisin production. Approximately

393 150 transformants were chosen at random for each single position (P9X and G10X) and 1152

394 transformants for the randomised P9XG10X bank. Isolated colonies were inoculated into 96-well  
395 plates containing GM17 Cm<sup>10</sup>, incubated overnight and stored at -20°C after addition of 80%  
396 glycerol. Deferred antagonism assays were performed by replicating strains on GM17 agar plates  
397 and allowing them to grow overnight before overlaying with GM17 agar (0.75% w/v agar)  
398 seeded with the *L. lactis* HP indicator strain. Induction assays were carried out by replicating  
399 strains from each 96 well plate into a fresh 96 well plate containing GM17 broth pre-inoculated  
400 with *L. lactis* NZ9000 pNZ8150gfp+, in which GFP acts as a reporter of expression from a nisin  
401 inducible promoter (24). Induction of GFP was monitored over 20 hours in terms of relative  
402 fluorescence units (RFU) using a TECAN Genios Fluorescence, Absorbance and Luminescence  
403 Reader using excitation and emission spectra of 485nm and 535nm, respectively.

404

#### 405 MALDI TOF Mass Spectrometry

406 For Colony Mass Spectrometry (CMS), bacterial colonies of P9X and G10X mutants were  
407 collected with sterile plastic loops and mixed with 50 µL of 70% IPA containing 0.1%  
408 Trifluoroacetic acid (TFA). The suspension was vortexed, the cells centrifuged in a benchtop  
409 centrifuge at 8260 g for 2 min and the supernatant was removed for analysis. For MALDI TOF  
410 Mass Spectrometry of nisin M cell free supernatant (CFS) was purified prepared as follows; a  
411 1% inoculum of nisin mutant producing strains were grown overnight in 50 mL clarified TY  
412 broth and incubated overnight at 30°C. Following incubation cells were centrifuged at 5000rpm  
413 for 20 mins at 4°C. Cell free supernatant (CFS) was removed and passed through a 1 g (6 mL)  
414 Strata C-18 E column (Phenomenex) pre-equilibrated with 6 mL methanol (Fisher Scientific,  
415 UK) and 6 mL HPLC grade H<sub>2</sub>O. The column was washed with 12 mL 30% ethanol and nisin  
416 eluted using 5 mL 70% isopropanol – 0.1% TFA. Mass Spectrometry in all cases was performed

417 with an Axima TOF<sup>2</sup> MALDI TOF mass spectrometer (Shimadzu Biotech, Manchester, UK). A  
418 0.5  $\mu$ L aliquot of matrix solution (alpha-cyano-4-hydroxycinnamic acid (CHCA), 10 mg mL<sup>-1</sup> in  
419 50% acetonitrile-0.1% (v/v) TFA) was placed onto the target and left for 1-2 min before being  
420 removed. The residual solution was then air dried and the sample solution (re-suspended  
421 lyophilised powder or CMS supernatant) was positioned onto the pre-coated sample spot. Matrix  
422 solution (0.5  $\mu$ L) was added to the sample and allowed to air-dry. The sample was subsequently  
423 analysed in a positive-ion linear mode.

424

#### 425 Purification of nisin A and nisin M

426 Purifications of nisin A and variant, nisin M were carried out as per a previously employed (33)  
427 with modifications. Briefly, overnight cultures of *L. lactis* NZ9800 pDF05*nisM* (APC3920)  
428 and *L. lactis* NZ9700 were inoculated at 0.5% into separate purified tryptone-yeast extract (TY)  
429 broth (2  $\times$  900 mL) supplemented with 20% glucose and 20%  $\beta$ -glycerophosphate, and incubated  
430 at 30°C overnight. Following incubation, the cultures were centrifuged at 6500g at 4°C for 15  
431 min. The supernatant was passed through a column containing ~70g Amberlite XAD-16 beads  
432 and subsequently washed with 500 mL of 30% ethanol. The nisin was eluted from the column  
433 using 70% isopropanol containing 0.1% trifluoroacetic acid (TFA). Simultaneously, bacterial  
434 cell pellets were resuspended in 300 mL 70% isopropanol – 0.1% TFA and stirred at room  
435 temperature for 3 h. This cell suspension was then centrifuged at 5000g at 4°C for 10 min and  
436 the supernatant was retained. The column eluant was pooled with the post-centrifugation  
437 supernatant and isopropanol evaporated using a rotary evaporator (BÜCHI Rotavapor R-205,  
438 Switzerland). The pH of the sample was adjusted to pH 4.0 and was subsequently passed through  
439 a 10 g (60 mL) Strata C-18 E column (Phenomenex) pre-equilibrated with 60 mL methanol

440 (Fisher Scientific, UK) and 60 mL HPLC grade H<sub>2</sub>O. After applying 120 mL 30% ethanol, nisin  
441 was eluted from the column using 60 ml 70% isopropanol – 0.1% TFA. For HPLC purification  
442 12 mL volumes were concentrated to a volume of 2 mL by rotary evaporation and applied to a  
443 Phenomenex C12 reverse-phase (RP-HPLC) column (Jupiter 4 µm proteo 90 Å, 250 mm × 10.0  
444 mm, 4 µm) previously equilibrated with 25% acetonitrile-0.1% TFA. Nisin was eluted via a  
445 gradient of 25–50% acetonitrile-0.1% TFA that was developed from 10–40 min at a flow rate of  
446 3.2 mL min<sup>-1</sup>. Nisin containing fractions were pooled and acetonitrile removed by rotary  
447 evaporation. The purified peptides were lyophilised and stored at -20°C.

448

#### 449 Minimum Inhibitory Concentration (MIC) Assays

450 MIC's were also carried out on strains into which the NICE system was reported to have been  
451 introduced including, *Lactobacillus plantarum* (*Lb. plantarum*) and *Lactobacillus brevis* (*Lb.*  
452 *brevis*) in order to determine the potential of nisin M as an alternative to nisin A in the NICE  
453 system.

454 Minimum inhibitory concentration determinations for strains were carried out in triplicate in 96  
455 well microtitre plates (Sarstedt) as described previously (34). Plates were pre-treated with bovine  
456 serum albumin (BSA) prior to addition of the peptides. Briefly, to each well of the microtitre  
457 plate 200 µL of phosphate buffered saline (PBS) containing 1% (w/v) bovine serum albumin  
458 (BSA) was added and incubated at 37°C for 30 min. The wells were washed with 200 µL PBS  
459 and allowed to dry. Target strains, *L. lactis* spp. cremoris HP, *L. lactis* NZ9000 pNZ8150*gfp*<sup>+</sup>  
460 were grown overnight in M17 broth (Sigma) supplemented with glucose (0.5%) at 30°C. *Lb.*  
461 *plantarum* and *Lb. brevis* were grown overnight in MRS broth (Oxoid) at 30°C. Strains were

462 sub-cultured into fresh broth and allowed to grow to an OD<sub>600</sub> of ~0.5, diluted to a final  
463 concentration of 10<sup>5</sup> cfu mL<sup>-1</sup> in a volume of 0.2 mL. Nisin A and nisin M peptides were  
464 adjusted to a 750 nM starting concentration and 2-fold serial dilutions of each peptide was added  
465 to the target strain. After incubation for 16 h at 30°C the MIC was read as the lowest peptide  
466 concentration causing inhibition of visible growth.

467

468 Comparison of nisin A and nisin M induction capacity using beta-galactosidase activity  
469 β-galactosidase activity assay was performed as previously employed (35) with modifications.  
470 Cultures of *L. lactis* NZ9000 pPTPLβgal<sup>+</sup> were inoculated in M17 broth (Sigma), supplemented  
471 with glucose at 0.5% (GM17) and tetracycline (10 μg mL<sup>-1</sup>), and incubated at 30°C overnight.  
472 Following incubation, a 1% inoculum of each replicate was sub-cultured into fresh GM17  
473 medium and incubated at 30°C until an OD<sub>600</sub> of 0.2-0.3 was reached. Cells were then treated  
474 separately with nisin A and nisin M purified peptides to a final concentration of 10 ng mL<sup>-1</sup>.  
475 Every hour 1 mL samples of each test were transferred to an eppendorf and centrifuged at 13,000  
476 rpm for 2 minutes (Sorvall Legend Micro 17 centrifuge, Thermo Scientific) to harvest cells.  
477 Cells were re-suspended in 1 mL lacZ buffer and 0.5 mL of this was treated with 12.5 μL of  
478 0.1% SDS and 25 μL of chloroform and incubated at 30°C for 5 minutes to dissolve cell  
479 membranes. Following incubation 100 μL of 2-Nitrophenyl-β-D-galactopyranoside (ONPG) (4  
480 mg mL<sup>-1</sup>) (Sigma-Aldrich) was added to each sample and incubated at 37°C until a yellow colour  
481 developed. To stop the reaction samples were treated with 250 μL of a 1 M sodium carbonate  
482 solution and centrifuged at 8000rpm for 5 minutes (Thermo Scientific). Absorbance readings of  
483 supernatant were read at OD<sub>420</sub> and OD<sub>550</sub> (SpectraMax M3 spectrophotometer, Molecular

484 Devices, Sunnyvale, California, USA). Measurement of  $\beta$ -galactosidase activity of samples was  
485 calculated as  $1000 \times (\text{OD}_{420} - [1.75 \times \text{OD}_{550}]) / (t \times v \times \text{OD}_{600})$  as previously described (16).  
486  
487 Assessment of purified nisin A and nisin M induction capacity using a green fluorescent protein  
488 reporter system.  
489 Induction assays were performed previously described (24) with modifications. Briefly, cultures  
490 of *L. lactis* NZ9000 pNZ8150*gfp*<sup>+</sup> were inoculated in M17 broth (Sigma), supplemented with  
491 glucose at 0.5% (GM17) with chloramphenicol ( $10 \mu\text{g mL}^{-1}$ ) and incubated at  $30^\circ\text{C}$  overnight.  
492 Following incubation, a 1% inoculum of each replicate was sub-cultured into fresh GM17  
493 medium and incubated at  $30^\circ\text{C}$  until an  $\text{OD}_{600}$  of  $\sim 0.5$  was reached. Cells were then diluted to a  
494 final concentration of  $10^5 \text{ cfu mL}^{-1}$  and treated with nisin A and nisin M at final concentrations of  
495  $10 \text{ ng mL}^{-1}$ ,  $50 \text{ ng mL}^{-1}$ ,  $100 \text{ ng mL}^{-1}$  and  $300 \text{ ng mL}^{-1}$ . Subsequently, 2 mL was transferred to  
496 black, 24 well microtitre plates (PerkinElmer) for induction and 200  $\mu\text{L}$  into a 96 well plate  
497 (Sarstedt) for absorbance readings. Fluorescence was detected using a SpectraMax M3  
498 spectrophotometer (Molecular Devices, Sunnyvale, California, USA) where excitation and  
499 emission parameters were set to 485nm and 528nm respectively for fluorescence, while  
500 absorbance readings were taken at  $\text{OD}_{595}$  using a Multiskan FC microplate photometer v1.01.14  
501 (Thermo Scientific, Waltham, Massachusetts, USA). Baseline absorbance of un-cultured GM17  
502 was subtracted from the fluorescence and absorbance readings of all test samples using SoftMax  
503 Pro v6.3 and SkanIt RE v4.1 software, respectively. Fluorescence was reported as relative light  
504 units (RLU) and absorbance as  $\text{OD}_{595\text{nm}}$ . Tests were carried out in triplicate.

505

506

507

508

509 Statistical analysis

510 Statistical analysis was carried out with SPSS Statistics v2. A test of normality was performed to  
511 determine data for each test was normally distributed. For normally distributed data a Repeated  
512 Measures ANOVA was performed. For data not normally distributed a Levene's test of  
513 homogeneity was performed, where if equal variances were assumed the Repeated Measures  
514 ANOVA was carried out; and if equal variances were not assumed the non-parametric Friedman  
515 test was performed to determine if differences between the two nisin variants induction capacity,  
516 and between the growth of the strains when induced with the peptides at higher concentrations  
517 compared to an un-induced control were significant. For ANOVA/Friedman's results with a  
518 significant difference between groups ( $P < .05$ ) a post hoc test was performed. Post hoc tests for  
519 normally distributed/equal variances assumed samples was the Bonferroni test, and for non-  
520 normally distributed/equal variances not assumed samples Dunnett's T3 test was performed. The  
521 significance threshold for all ANOVA's and non-parametric tests performed was set at .05.

639

640

641 Table 2: MIC of nisin A and nisin M against standard indicator strains (including those reported  
642 to have had the NICE system introduced).

Indicator organism	Nisin A $\mu\text{g mL}^{-1}$ ( $\mu\text{M}$ )	Nisin M $\mu\text{g mL}^{-1}$ ( $\mu\text{M}$ )	Fold decrease in activity
<i>Lb. plantarum</i> UCC16	0.625 (0.1875)	>2.5 (>0.750)	>4
<i>L. lactis</i> NZ9000 pNZ8150gfp+	0.156 (0.046)	>2.5 (>0.750)	>16

<i>L. lactis</i> NZ9000	0.156 (0.046)	2.5 (0.750)	16
pNZ8150			
<i>Lb. brevis</i> SA-C12	0.078 (0.0234)	1.25 (0.375)	16
<i>L. lactis</i> spp. <i>cremoris</i> HP	0.156 (0.0468)	2.5 (0.750)	16

643

644

645 Table 3: Bacterial strains and plasmids used in this study

Strain or Plasmid	Characteristic	Reference
<i>L. lactis</i> NZ9000	MG1363 derivative, <i>NisRK</i> integrated into <i>pepN</i> gene ( <i>pepN</i> -). Most commonly used host of the NICE system.	(22) (4)
<i>L. lactis</i> NZ9000 pNZ8150	NZ9000 strain harbouring pNZ8150. pNZ8150: <i>ScaI</i> site for translational fusions, standard vector for NICE system, Cm <sup>R</sup> .	(4)
<i>L. lactis</i> NZ9000 pNZ8150 <i>gfp</i> <sup>+</sup>	NZ9000 strain harbouring pNZ8150 <i>gfp</i> <sup>+</sup> under <i>PnisA</i> promoter. Cm <sup>R</sup> .	(24)
<i>L. lactis</i> NZ9000 pPTPL <i>βgal</i> <sup>+</sup>	NZ9000 strain harbouring low copy plasmid pPTPL with $\beta$ -galactosidase expressing gene under the control of the <i>PnisA</i> promoter. Tet <sup>R</sup>	(7)
<i>L. lactis</i> NZ9800	Derivative of NZ9700 with 4bp deletion rendering an inactive nisin operon ( $\Delta$ <i>nisA</i> ), except <i>nisRK</i> genes. Host of the NICE system.	(22, 36)
<i>L. lactis</i> NZ9800 pDF05	NZ9800 harbouring pDF05 (pCI372 with <i>nisA</i> under its own promoter). Wild type nisin A producer, Cm <sup>R</sup> .	(22, 36) (7)

<i>L. lactis</i> NZ9800 pDF05 <i>nisM</i>	pDF05 where codons 9 and 10 of <i>nisA</i> have been randomized. Nisin M producer, Cm <sup>R</sup> .	This work UCC Culture Collection (APC3920)
<i>Lb. plantarum</i> UCC16	Nisin sensitive indicator Species in which NICE system has been utilized.	UCC Culture Collection (4, 19)
<i>Lb. brevis</i> SA-C12	Nisin sensitive indicator Species in which NICE system has been utilized.	UCC Culture Collection (4, 37)
<i>L. lactis</i> ssp. <i>cremoris</i> HP	Nisin sensitive indicator strain	UCC Culture Collection

665 shown as percentages (%) and ordered from highest to lowest based on biological activity of the  
666 variants.

667

668 Figure 2. A: (Top) Biological activity of nisin A and nisin M as determined by deferred  
669 antagonism assays and assessment of induction capacity following induction of a *L. lactis* strain  
670 containing *gfp*<sup>+</sup> under control of the nisin promoter. (Bottom) Colony Mass Spectrometry of the  
671 wild type nisin A producer (3353.44 Da) and nisin M comprising of a combination of  
672 unmodified peptide, single dehydration or two dehydrations at P9T/G10T (3399.86 Da, 3382.91  
673 Da, and 3365.33 Da respectively). B: Structure of nisin A where amino acids are represented by  
674 their single letter codes and modified residues are indicated as follows; Dha: dehydroalanine,  
675 Dhb: dehydrobutyrine, Abu: 2-aminoabutyric acid, Ala-S-Ala: lanthionine, Abu-S-Ala:  
676 methylanthionine. Residues in orange and pink show amino acid substitutions for nisin M,  
677 producing 4 possible forms of the peptide.

678

679 Figure 3. Induction capacity of nisin A (red/circle) and nisin M (blue/square) determined by  
680 expression of (A) GFP and (B)  $\beta$ -galactosidase reporter genes under the control of the *PnisA*  
681 promoter in *L. lactis* NZ9000 pNZ8150*gfp*<sup>+</sup> and *L. lactis* NZ9000 pPTPL *$\beta$ gal*<sup>+</sup> respectively  
682 when induced at a final concentration of 10 ng mL<sup>-1</sup>. Negative controls (green/triangle) are  
683 uninduced test strains. Statistical analysis shows there is no significant difference between the  
684 induction capacities of nisin M and nisin A in both methods tested ( $P > .05$ ).

685

686 Figure 4. Comparison of induction capacities of nisin A (red/circle), nisin M (blue/square)  
687 determined by expression of GFP under the control of the *PnisA* promoter in *L. lactis*  
688 pNZ8150*gfp*<sup>+</sup> induced at final concentrations of (A) 50 ng mL<sup>-1</sup>, (B) 100 ng mL<sup>-1</sup> and (C) 300  
689 ng mL<sup>-1</sup>. Statistical analysis demonstrates a significant difference between induction capacity of  
690 the two peptides at all concentrations tested, ( $P < .0005$ ) Negative control in this assay is  
691 uninduced *L. lactis* NZ9000 pNZ8150*gfp*<sup>+</sup> (green/triangle).

692

693 Figure 5. Effects of nisin A (red/circle) and nisin M (blue/square) on growth of *L. lactis* NZ9000  
694 pNZ8150*gfp*<sup>+</sup> induced at concentrations of (A) 50 ng mL<sup>-1</sup>, (B) 100 ng mL<sup>-1</sup> and (C) 300 ng mL<sup>-1</sup>  
695 compared to an un-induced control (green/triangle) determined by absorbance at OD<sub>595nm</sub>.  
696 Results show no significant difference between growth of the uninduced control and cells  
697 induced with nisin M at all concentrations tested ( $P > .05$ ); while there is a significant difference  
698 between the growth of cells induced with WT nisin compared to both the uninduced control (50  
699 ng mL<sup>-1</sup>:  $P < .0005$ ; 100 ng mL<sup>-1</sup>:  $P < .0005$ ; 300 ng mL<sup>-1</sup>:  $P < .0005$ ), and samples induced with  
700 nisin M (50 ng mL<sup>-1</sup>:  $P < .05$ ; 100 ng mL<sup>-1</sup>:  $P < .0005$ ; 300 ng mL<sup>-1</sup>:  $P < .0005$ ).
