## 20 Abstract

| 21 | Nisin A is a potent antimicrobial with potential as an alternative to traditional antibiotics, and a   |
|----|--|
| 22 | number of genetically modified variants have been created that target clinically relevant              |
| 23 | pathogens. In addition to antimicrobial activity, nisin auto-regulates its own production via a        |
| 24 | signal transduction pathway, a property that has been exploited in a protein expression system         |
| 25 | termed the Nisin Controlled Gene Expression (NICE) system. Although NICE has become one                |
| 26 | of the most popular protein expression systems, one drawback is that the inducer peptide, nisin        |
| 27 | A, also has inhibitory activity. It has already been demonstrated that the N-terminal region of        |
| 28 | nisin A contributes to antimicrobial activity and signal transduction properties, therefore, we        |
| 29 | conducted bioengineering of nisin at positions Pro9 and Gly10 within ring B to produce a bank          |
| 30 | of variants that could potentially be used as alternative induction peptides. One variant,             |
| 31 | designated nisin M, has threonines at positions 9 and 10 and retains induction capacity                |
| 32 | comparable to the wild type nisin A, while most of the antimicrobial activity is abolished.            |
| 33 | Further analysis confirmed that nisin M produces a mix of peptides as a result of different            |
| 34 | degrees of dehydration of the two threonines. We show that nisin M exhibits potential as a more        |
| 35 | suitable alternative to nisin A for the expression of proteins that may be difficult to express, or to |
| 36 | produce proteins in strains that are sensitive to wild type nisin. Moreover, it may address the        |
| 37 | increasing demand by industry for optimization of peptide fermentations to increase yields or          |
| 38 | their production rate.   |

39

41 42

| 44 | This study describes the generation of a nisin variant with superior characteristics for use in the |
|----|---|
| 45 | NICE protein expression system. The variant, termed nisin M, retains an induction capacity          |
| 46 | comparable to the wild type nisin A but exhibits significantly reduced antimicrobial activity and   |
| 47 | can therefore be used at concentrations that are normally toxic to the expression host.             |

Applied and Environmental Microbiology 3

| 63 | Producing high quantities of proteins of biotechnological and pharmaceutical value from their     |
|----|---|
| 64 | natural sources can have economic challenges. Although Escherichia coli has been the dominant     |
| 65 | player in the production of recombinant proteins for decades, several issues including the        |
| 66 | presence of endotoxin or lipopolysaccharide requires expensive and often problematic              |
| 67 | downstream purification processes (1). The lactic acid bacteria (LAB) Lactococcus lactis has      |
| 68 | gained importance as a host for heterologous protein expression due to its well understood        |
| 69 | genetics and metabolism, generally regarded as safe (GRAS) status, as well as the availability of |
| 70 | a wide range of genetic tools. Indeed, a major advance with regards to protein expression in L.   |
| 71 | lactis was the discovery and use of gene expression systems based on a number of inducible        |
| 72 | promoters. These include promoters that respond to the environment such as P170, which is         |
| 73 | upregulated at low pH (2) and zinc-based systems that respond to zinc availability (3). One of    |
| 74 | the best known and most widely employed expression systems is the nisin-inducible controlled      |
| 75 | gene expression (NICE) system (4, 5) which stems from the nisin biosynthetic operon               |
| 76 | (nisABTCIPRKFEG) found in some L. lactis strains (6). Nisin is a 34 amino acid peptide and is     |
| 77 | the most extensively studied bacteriocin (ribosomally synthesized, antimicrobial peptides         |
| 78 | produced by bacteria) (7, 8). It targets a wide range of Gram-positive bacteria, including food   |
| 79 | pathogens such as Listeria monocytogenes, Staphylococcus aureus, Bacillus cereus and clostridia   |
| 80 | (9, 10). Nisin induces its own biosynthesis via a two-component signal transduction pathway       |
| 81 | NisRK (6) and has led to the development and application of a food grade expression system        |
| 82 | using L. lactis as the host (11). The NICE system encompasses both regulatory elements of the     |
| 83 | nisin operon, PnisA, the nisin-inducible promoter (cloned into several expression vectors) and    |
| 84 | nisRK, the two component histidine kinase response regulator system (harboured by compatible      |

| 85  | plasmids or inserted on the chromosome of a suitable host strain). The system is 'switched on'    |
|-----|---|
| 86  | by the addition of nisin in the nanomolar range which activates the receptor NisK. NisK activates |
| 87  | NisR by phosphorylation and the activated NisR induces expression at the nisin A promoter (4).    |
| 88  | The NICE system has been extensively used to produce proteins in L. lactis, such as               |
| 89  | bacteriophage lysins and metalloendopeptidases to demonstrate their potential in dairy            |
| 90  | fermentations (12, 13). Moreover, NICE can, under certain conditions and with some                |
| 91  | modifications to the system components, also be used in other species of LAB and in other         |
| 92  | Gram-positive bacteria (11, 14). Its numerous advantages include ease of use, exquisitely         |
| 93  | controlled and efficiently induced expression and amenability to large-scale production           |
| 94  | processes. As an example, nisin induced fermentations of the antimicrobial lysostaphin have       |
| 95  | been carried out and even identified areas of the NICE system that need improvement (5).          |
| 96  | However, for industrial applications, nisin addition remains costly (15). Another drawback of the |
| 97  | system is that the inducing peptide is also toxic due to its potent antimicrobial activity.       |
| 98  | Therefore, a nisin peptide that retains its induction capacity whilst having little to no         |
| 99  | antimicrobial activity would be highly desirable. The gene-encoded nature of the nisin peptide    |
| 100 | makes genetic engineering to develop certain characteristics of the molecule an attractive and    |
| 101 | feasible option. Although the bioengineering of nisin commenced over three decades ago, the       |
| 102 | majority of studies have largely focused on identifying nisin variants with enhanced              |
| 103 | antimicrobial activity or an extended-antimicrobial spectrum (10, 16, 17). The importance of the  |
| 104 | N-terminus rings A and B with respect to induction has been highlighted on a number of            |
| 105 | occasions (6, 16, 18). These studies involved either combinatorial saturation mutagenesis of      |
| 106 | rings A and B (18) or the application of alanine scanning approaches to assess the antimicrobial  |
| 107 | activity and induction properties of various nisin derivatives (16).                              |
|     |   |

| 109 | of nisin derivatives that have been randomized at positions 9 (P9X) and 10 (G10X) individually    |
|-----|---|
| 110 | and in combination (P9XG10X) and assessed them for antimicrobial activity in conjunction with     |
| 111 | their ability to induce the nisin promoter using GFP and $\beta$ -galactosidase reporter systems. |

#### 127 Results

128 Creation and screening nisin derivatives for antimicrobial activity and induction capacity.

129 Previous studies utilising site-directed and alanine scanning mutagenesis of nisin have revealed 130 that the N-terminal ring structures are an important region required to activate NisRK (16, 18). In 131 particular, mutagenesis of ring B has been shown to modulate antimicrobial and induction 132 activity. We selected this location as a suitable target for the generation of variants to screen for 133 our desired activities. In order to fully exploit the potential of the nisin ring B we undertook a complete randomisation of the two amino acids in Pro9 and Gly10, both alone (P9X, G10X) and 134 in combination (P9XG10X) using NNK scanning of both codons in the nisin A structural gene 135 (nisA) as previously described (7). A bank consisting of 1,452 individual variants created in L. 136 lactis NZ9800 pCI372nisA (pDF05) were screened for antimicrobial activity using deferred 137 antagonism agar diffusion assays and their ability to induce the nisin promoter, PnisA fused to a 138 139 gfp reporter gene. The impact of mutations targeting position nine (proline) on antimicrobial activity was assessed using an overlay assay and resulted in zones ranging from those 140 141 comparable to the wild type control to those devoid of any observable activity. Analysis of 142 colonies using mass spectrometry and/or DNA sequencing identified 12 different amino acid substitutions corresponding to P9H, P9E, P9S, P9T, P9N, P9A, P9M, P9I, P9V P9L, P9W, and 143 144 P9F (Figure 1A). Substituting P9 with an alanine (P9A) had no impact on either antimicrobial activity or induction capacity. A number of variants (P9H, P9E, P9W and P9F) displayed a loss 145 of both properties. Several others (P9M, P9L, P9N, P9V and P9I) displayed a significant 146 reduction in antimicrobial activity (between 50-65% of wild type) as well as a reduced ability to 147 148 induce the gfp reporter. Notably, P9T and P9S exhibited a slight reduction in antimicrobial

149 activity (70-75%) but retained 100% and 75% induction capacity respectively compared to the 150 wild type control (Figure 1A), which was in agreement with previous studies (16, 18). It is 151 significant that replacement of P9 with either threonine or serine introduces hydroxylated residues which could act as substrates for the lanthionine modification machinery. Indeed, 152 colony mass spectrometry (CMS) of the P9T and P9S producers revealed the presence of masses 153 154 corresponding to the presence of both unmodified (threonine or serine) and modified residues 155 (dehydrobutyrine (Dhb) or dehydroalanine (Dha)) (Table1). 156 Analysis of 144 variants where position 10 (glycine) was targeted, revealed that the majority of 157 clones exhibited either wild type activity or displayed a complete loss of both antimicrobial activity and induction capacity. Mass Spectrometry (MS) and DNA sequencing determined that 158 159 almost all of the active variants had retained the original glycine at position 10 (wild type), but 160 we also detected variants corresponding to G10T and G10S (Figure 1B). Here too, CMS identified a mixture of both modified and non-modified residues in the case of G10S (i.e. G10S 161 162 and G10Dha) but this was not observed when threonine was present at position 10. A variant that 163 displayed little reduction in activity (>50%) had an alanine (G10A) substitution (Figure 1B). A 164 selection of variants that lacked both antimicrobial activity and induction capacity were subjected to DNA sequencing analysis, which identified substitutions corresponding to G10F, 165 G10W and G10L. The inability to detect as wide a range of active variants at this position may 166 arise from the fact that several variants in this position (including G10D, G10N, G10H, G10R, 167 168 G10L and G10P) have been linked with the loss of threonine dehydration at position 8, meaning 169 that ring B does not undergo cyclization (18).

We then set out to vary both residues 9 and 10 simultaneously. As expected, screening of the
doubly randomized P9XG10X bank revealed far fewer bioactive variants (approx. 5.6% of the

| 172 | total) of which the majority were wild type (38/64). The remainder exhibited varying degrees of |
|-----|---|
| 173 | antimicrobial activity ranging from 10-50% with a concomitant loss in induction capacity (data  |
| 174 | not shown). However, one clone was conspicuous in that despite its apparent lack of             |
| 175 | antimicrobial activity, it retained an induction capability comparable to the wild type nisin A |
| 176 | (Figure 2A). DNA sequencing analysis revealed a variant corresponding to P9T/G10T (both         |
| 177 | residues replaced with a threonine, Fig 2B). Furthermore, CMS revealed the presence of masses   |
| 178 | corresponding to the doubly-modified TT peptide (Dhb9Dhb10) but also species with one           |
| 179 | modified residue to Dhb and a mass close to a peptide with no modified threonine residues       |
| 180 | (Figure 2A; Table 1). Purification of the derivative P9T/G10T, we termed nisin M, was carried   |
| 181 | out with our standard nisin purification protocol and subsequent high-performance liquid        |
| 182 | chromatography (HPLC) evaluation revealed the presence of two major peaks (data not shown).     |
| 183 | Mass spectrometry analysis of these fractions revealed the presence of one peptide of 3365 Da   |
| 184 | (consistent with the presence of two Dhb's) and a second peptide of 3383 Da (consistent with a  |
| 185 | peptide with one threonine and one Dhb). Additionally, a mass in close agreement to a non-      |
| 186 | modified peptide with threonines in both positions was also observed (data not shown).          |
| 187 |   |
| 188 | Minimum inhibitory concentration (MIC) of nisin M   |

Following HPLC and freeze-drying of combined fractions to obtain pure peptides, MIC assays were carried out using equimolar concentrations of nisin A and nisin M against a range of Gram positive targets including genera into which the NICE system has been previously introduced (Table 2). The MIC was determined to be the lowest concentration of peptide that resulted in the absence of visible growth of the target strain after 16 hours under the appropriate growth conditions. We established that the MIC of nisin M against a standard laboratory indicator *L*. Applied and Environmental

Microbioloav

| 195 | <i>lactis</i> HP was 2.5 µg mL <sup>-1</sup> , reflecting a 16-fold increase in MIC compared to wild type nisin A          |
|-----|--|
| 196 | $(0.156 \ \mu g \ mL^{-1})$ . Nisin M displayed a similar decrease in potency against the <i>L. lactis</i> NZ9000          |
| 197 | gfp reporter strain and its isogenic equivalent L. lactis NZ9000 (Table 2). Several lactobacilli                           |
| 198 | have been used as hosts of the NICE system including Lactobacillus plantarum, Lactobacillus                                |
| 199 | helveticus and Lactobacillus brevis (14, 19). When Lb. plantarum UCC16 and Lb. brevis SA-                                  |
| 200 | C12 were assessed, an MIC of >2.5 $\mu$ g mL <sup>-1</sup> and 1.25 $\mu$ g mL <sup>-1</sup> was observed, demonstrating a |
| 201 | >4-fold and 16-fold decrease in antimicrobial activity for nisin M respectively in comparison to                           |
| 202 | wild type peptide. (Table 2).  |
|     |  |

203

Induction capacity of nisin A and nisin M at 10 ng mL<sup>-1</sup> 204

Determination of the induction capacity of nisin A and nisin M at a concentration of 10 ng mL<sup>-1</sup> 205 206 was performed using two reporter systems, by way of measurement of GFP and  $\beta$ -galactosidase 207 production. There was no statistical difference in the dynamics of RLU detection when the GFP reporter strain was induced with nisin A and nisin M (P > .05) (Figure 3A). Similarly, induction 208 209 of the  $\beta gal$  + reporter strain also revealed no significant difference between nisin A and nisin M at equivalent concentrations (10 ng mL<sup>-1</sup>) (P > .05) (Figure 3B). Moreover, the rate of expression, 210 211 and therefore the rate of induction was identical for both nisin A and nisin M under the

212 conditions tested in both GFP and  $\beta$ -galactosidase assays.

213

214 Induction capacity and effect on growth of nisin reporter strain at higher induction

215 concentrations

| 216   | Next, we employed 50 ng mL <sup>-1</sup> , 100 ng mL <sup>-1</sup> and 300 ng mL <sup>-1</sup> of peptide to determine the effect  |
|---|--|
| 217   | of higher concentrations of nisin A and M on both protein expression and on growth of the  |
| 218   | expression host. Fluorescence (RLU) was measured to determine GFP expression and   |
| 219   | absorbance readings at OD <sub>595nm</sub> were taken to observe growth of induced strains. For each of  |
| 220   | these higher concentrations a significant difference between the level of induction by nisin A and   |
| 221   | nisin M ( $P < .0005$ ) was noted (Fig. 4A-C). Interestingly, the highest RLU reading attained was   |
| 222   | from cells induced with nisin M at a final concentration of 50 ng mL <sup>-1</sup> . At this concentration   |
| 223   | induction continued for the course of the experiment (18 hrs), whereas at 100 ng mL <sup>-1</sup> and 300 ng   |
| 224   | mL <sup>-1</sup> induction reached maximum and decreased after 10-12 hours. Notably, there was no delay  |
| 225   | in the rate of GFP expression following induction with nisin M at 50 ng mL <sup>-1</sup> and 100 ng mL <sup>-1</sup>   |
| 226   | (Figure 4A-B) compared to 10 ng mL <sup>-1</sup> (Figure 3A), where fluorescence intensifies at  |
| 227   | approximately 6 hours post induction for all experiments; meanwhile, there was a minor delay of  |
| 227   |  |
| 228   | 30 minutes in expression with induction at 300 ng mL <sup>-1</sup> (Figure 4C).  |
|   |  |
| 228   | 30 minutes in expression with induction at 300 ng mL <sup>-1</sup> (Figure 4C).  |
| 228<br>229  | 30 minutes in expression with induction at 300 ng mL <sup>-1</sup> (Figure 4C).<br>When the effects on growth were analysed, no significant impact on the growth of the GFP  |
| 228<br>229<br>230   | 30 minutes in expression with induction at 300 ng mL <sup>-1</sup> (Figure 4C).<br>When the effects on growth were analysed, no significant impact on the growth of the GFP reporter strain was observed following induction with nisin M at 50 ng mL <sup>-1</sup> ( $P$ > .05), 100 ng   |
| 228<br>229<br>230<br>231                                    | 30 minutes in expression with induction at 300 ng mL <sup>-1</sup> (Figure 4C).<br>When the effects on growth were analysed, no significant impact on the growth of the GFP reporter strain was observed following induction with nisin M at 50 ng mL <sup>-1</sup> ( $P$ > .05), 100 ng mL <sup>-1</sup> ( $P$ > .05) and 300 ng mL <sup>-1</sup> ( $P$ > .05). The OD <sub>595</sub> of both non-induced cells and cells induced   |
| 228<br>229<br>230<br>231<br>232                             | 30 minutes in expression with induction at 300 ng mL <sup>-1</sup> (Figure 4C).<br>When the effects on growth were analysed, no significant impact on the growth of the GFP reporter strain was observed following induction with nisin M at 50 ng mL <sup>-1</sup> ( $P$ > .05), 100 ng mL <sup>-1</sup> ( $P$ > .05) and 300 ng mL <sup>-1</sup> ( $P$ > .05). The OD <sub>595</sub> of both non-induced cells and cells induced with nisin M increased approximately 5 hours post induction. However, induction with nisin A at   |
| 228<br>229<br>230<br>231<br>232<br>233                      | 30 minutes in expression with induction at 300 ng mL <sup>-1</sup> (Figure 4C).<br>When the effects on growth were analysed, no significant impact on the growth of the GFP reporter strain was observed following induction with nisin M at 50 ng mL <sup>-1</sup> ( $P$ > .05), 100 ng mL <sup>-1</sup> ( $P$ > .05) and 300 ng mL <sup>-1</sup> ( $P$ > .05). The OD <sub>595</sub> of both non-induced cells and cells induced with nisin M increased approximately 5 hours post induction. However, induction with nisin A at the same concentrations resulted in a significant lag-time in growth. An increase in OD <sub>595</sub> was  |
| 228<br>229<br>230<br>231<br>232<br>233<br>233               | 30 minutes in expression with induction at 300 ng mL <sup>-1</sup> (Figure 4C).<br>When the effects on growth were analysed, no significant impact on the growth of the GFP reporter strain was observed following induction with nisin M at 50 ng mL <sup>-1</sup> ( $P$ >.05), 100 ng mL <sup>-1</sup> ( $P$ >.05) and 300 ng mL <sup>-1</sup> ( $P$ >.05). The OD <sub>595</sub> of both non-induced cells and cells induced with nisin M increased approximately 5 hours post induction. However, induction with nisin A at the same concentrations resulted in a significant lag-time in growth. An increase in OD <sub>595</sub> was not observed until 7.5, 8 and 10 hours post induction at 50 ng mL <sup>-1</sup> ( $P$ <.05 for comparison of  |

#### 241 Discussion

242 Any new technological advancements to improve the production of protein biopharmaceuticals 243 and industrial enzymes by microorganisms is highly desirable. Potential methods to optimize the efficiency of an inducible gene expression system may involve adjustment of inducer dosage 244 and/or the timing of inducer addition. The Gram-positive NICE system is somewhat unusual in 245 246 that the inducer peptide also has the capacity to kill the expression host, and thus induction and 247 killing capacity must be balanced. The generation of a nisin derivative that retained its induction properties but with reduced antimicrobial properties would represent a significant improvement 248 249 to the NICE system that could be applied to more sensitive strains.

Previous work, where the focus has been on the nisin peptide itself, involved randomised 250 251 mutagenesis of rings A and B (18) and described mutants that retained considerable auto-252 induction abilities but with lower antimicrobial properties (and vice- versa). Similarly, Ge and 253 co-workers (2016) applied a complete alanine scanning mutagenesis approach and reported that the N-terminal ring structures (ring A and ring B) in nisin were involved in activating NisK to 254 255 act as an inducing molecule (16). In this study we focused our attention on ring B with a more 256 systematic mutagenesis approach to identify novel derivatives with altered activity/induction 257 properties. This proved to be successful in that we identified a nisin variant that retains induction capacity that is comparable to the wild type peptide but exhibits significantly less antimicrobial 258 259 activity.

| 261  | lanthionine ring structure but does not induce PnisA. Indeed, in the study by Steiß, Korn, Kötter   |
|--|---|
| 262  | and Entian (2015) the failure of subtilin to induce the histidine kinase NisK was shown to mostly   |
| 263  | depend on the presence of an N-terminal tryptophan, as its replacement with the aliphatic amino   |
| 264  | acid residues isoleucine, leucine, and valine led to activation of NisK (20). This suggests further   |
| 265  | bioengineering at position 1 and indeed other amino acid locations in the nisin M background  |
| 266  | could potentially enhance induction and reduce antimicrobial activity even further.   |
| 267  | Although this study highlighted ring B of nisin as a critical region in our quest to separate   |
| 268  | antimicrobial activity from induction/pheromone activity, more residue positions could and  |
| 269  | should be targeted. Studies with the natural variant nisin Z have revealed that derivatives   |
| 270  | corresponding to T2S and M17W exhibited an 11-fold and 2-fold increase in induction capacity  |
| 271  | relative to the parent peptide, respectively, while derivatives S5T and S3T had significantly   |
|  |   |
| 272  | reduced induction capacity (7).   |
| 272<br>273   | reduced induction capacity (7).<br>A computational approach evaluating the antimicrobial activity, induction capacity, production   |

Notably, another lantibiotic, subtilin is structurally closely related to nisin and contains the same

| 283  | While this might advocate for the use of nisin P as an alternative inducer to nisin A, the peptide   |
|--|--|
| 284  | does not induce at the lower and commonly used inducing concentration (10 ng mL <sup>-1</sup> ). Notably,  |
| 285  | the nisin M mutant generated in this study induces at both low and high concentrations. While  |
| 286  | no significant difference in growth of the induced strain compared to the un-induced control was   |
| 287  | observed, even at the maximum concentration applied (300 ng mL <sup>-1</sup> ), further evaluation with  |
| 288  | even higher concentrations of nisin M are necessary and with a variety of expression host strains.   |
| 289  | However, the practicality of using such high concentrations in terms of industrial applications  |
| 290  | would need to be considered, given that cell free supernatant from a nisin M producer would be   |
| 291  | the most likely option for induction (rather than expensive purified nisin peptides); though a   |
| 292  | fermentate analogous to nisaplin (2.5% nisin A) would enable a range of concentrations to be   |
| 293  | applied irrespective of the sensitivity of host strains (e.g. induction levels above 10 ng mL <sup>-1</sup> nisin  |
| 294  | A results in inhibitory effects on the expression strain L. lactis NZ9000) (22).   |
|  |  |

Other regions of nisin subjected to bioengineering approaches and<br>shown to impact on induction activity include the C-terminus and in particular serine and |

Applied and Environmental Microbiology some insight through mutational analysis of NisK. Mutagenesis of conserved residues in the
 extracellular region of NisK revealed that several hydrophobic residues including two aromatic
 residues (Tyr113 and Phe133) are crucial for NisK in sensing nisin and regulating nisin

309 biosynthesis (25).

310 Elimination of the antimicrobial activity of nisin is a priority when aiming to improve the nisin peptide in terms of its suitability as a peptide inducer, such as in the NICE system. For example, 311 Reunanen & Saris (2003) developed a method for the quantification of nisin in food samples, 312 313 through the construction of a non-nisin producing L. lactis strain (LAC240), with a plasmid 314 containing a gfp gene under the control of the nisF promoter and the constituent genes of the nisin two-component regulatory system, nisRK. It was reported that upon the addition of nisin 315 peptide concentrations greater than 20 ng mL<sup>-1</sup>, the LAC240 cells became stressed resulting in a 316 reduction in the quantity of GFP produced and the signal reached the background level when the 317 concentration of nisin was approximately 60 ng mL<sup>-1</sup> (26). Moreover, in a study that aimed to 318 improve the response of L. lactis to freezing damage through expression of an antifreeze peptide 319 320 (SF-P), the recombinant strain L. lactis NZ3900 SF-P was incubated with different concentrations of nisin (25, 50, or 100 ng mL<sup>-1</sup>) and at various pH and growth temperature 321 values (27). Notably, maximal expression was observed at 25 ng mL<sup>-1</sup>, with a much lower level 322 of expression at 50 ng mL<sup>-1</sup> and virtually no expression at 100 ng mL<sup>-1</sup>, most likely due to the 323 inhibitory effects of nisin A, though pH and temperature values were also a factor (27). In 324 325 another study that sought to optimize the NICE system for the expression of lysostaphin for both 326 laboratory (1 L) and industrial-scale (3000 L) applications and at high cell densities, the authors 327 noted that the addition of too much nisin was detrimental for product formation. Notably, when the culture was induced at higher cell densities, 160 mg L<sup>-1</sup> lysostaphin was formed with 20 ng 328

| 329 | mL <sup>-1</sup> nisin and 220 mg L <sup>-1</sup> lysostaphin was produced when 40 ng mL <sup>-1</sup> nisin was used for |
|-----|---|
| 330 | induction, indicative of a clear correlation between the cell density at induction and the amount                         |
| 331 | of nisin that is needed for maximal induction (5). While this group reported that maximum                                 |
| 332 | protein yield in the NICE system is achieved by induction carried out at a cell density of $OD_{600}$ =                   |
| 333 | 5 with a final concentration of 40 ng mL <sup>-1</sup> of nisin, we suggest that Nisin M provides for a                   |
| 334 | greater flexibility with respect to inducer concentration by virtue of the attenuated antimicrobial                       |
| 335 | activity of the peptides and the application of high concentrations of inducer peptide is not now a                       |
| 336 | limiting factor.  |
| 337 | To date, a multitude of peptides, enzymes and vaccines of clinical and biotechnological interest                          |
| 338 | have been overexpressed using nisin, including the anti-bacterial protein lysostaphin (5), a                              |
| 339 | haemagglutinin of the H5N1 influenza virus (28) and Rotavirus VP6 Protein (29), to name but a                             |
| 340 | few. Though several improvements have been made to the NICE system, further improvements                                  |
| 341 | are possible. For example, streamlined-genome mutants of L. lactis NZ9000 were generated by                               |
| 342 | deletion of four large nonessential DNA regions accounting for 2.83% of the genome and                                    |
| 343 | evaluated as microbial cell factories for recombinant protein production. Indeed, following nisin                         |
| 344 | induction, not only was the transcriptional efficiency improved but also the production levels of                         |
| 345 | the expressed reporters were approximately three to fourfold enhanced compared with the wild                              |
| 346 | strain (30). Additionally, expression from the $\Delta lacF$ host-strain L. lactis NZ3900 (a strain unable                |
| 347 | to utilize lactose), enabled food-grade, lactose-based plasmid selection and induction (31) whilst                        |
| 348 | deletion of a specific proteinase gene (NZ9000 $\Delta htrA$ ) led to increased stability of heterologous-                |
| 349 | secreted proteins (32).   |
| 350 | While the aforementioned studies focused on improving the host strain for expression of                                   |

351 proteins, this study focuses on potential improvements that can be made to the inducing peptide

| 353 | induction capacity (16, 18). This study has demonstrated that a nisin A variant with                     |      |
|-----|--|------|
| 354 | modifications to ring B retained comparable induction capacity to the wild type nisin A peptic           | de   |
| 355 | yet exhibited less inhibitory effects on the growth of the strain L. lactis NZ9000 when applied          | l at |
| 356 | concentrations as high as 300 ng mL $^{-1}$ (0.09 $\mu M$ ). It was also determined this combination has | s    |
| 357 | between >4 and >16 fold less activity against various genera and species of bacteria into whic           | h    |
| 358 | the NICE system has been introduced, therefore supporting the claim that nisin M exhibits                |      |
| 359 | potential as a suitable alternative to nisin A for use in the NICE system.                               |      |
| 360 | This study confirms that random mutagenesis experiments continue to be beneficial with a vie             | ew   |
| 361 | to enhancing the functional properties of the nisin peptide for specific applications and provid         | le   |
| 362 | novel nisin variants that exhibit potential for future applications in the pharmaceutical,               |      |

Materials and Methods:

Bacterial strains and plasmids

| 381 | mutagenesis was carried out using pDF05 (pCI372-nisA) as template and using oligonucleotides           |
|-----|--|
| 382 | as listed in (Table 4) containing an NNK codon in place of each native codon. PCR amplification        |
| 383 | was performed in a total volume of 50 µL with 0.5 ng of target DNA (pCI372-nisA), 1 unit               |
| 384 | Phusion High-Fidelity DNA polymerase (Finnzymes, Finland), 1 mM dNTPs and 500 ng each of               |
| 385 | the appropriate forward and reverse oligonucleotides. The reaction was pre-heated at 98°C for          |
| 386 | 2 min, and then incubated for 29 cycles at 98°C for 30 s, 55°C for 15 s and 72°C for 3 min 30 s,       |
| 387 | and then finished by incubating at 72°C for 3 min 30 s. Amplified products were treated with           |
| 388 | Dpn1 (Stratagene) for 60 min at 37°C to digest template DNA and purified using the QIAquick            |
| 389 | PCR purification kit. Following transformation of <i>E. coli</i> Top 10 cells plasmid DNA was isolated |
| 390 | and sequenced using primers pCI372FOR and pCI372REV (Table 4) to verify that mutagenesis               |
| 391 | had taken place. The purified products were subsequently introduced by electroporation into the        |
| 392 | strain L. lactis NZ9800 which has all the genes necessary for nisin production. Approximately          |
| 393 | 150 transformants were chosen at random for each single position (P9X and G10X) and 1152               |
|     |  |

Mutagenesis of the nisA gene was carried out as described previously (7). Briefly, saturation

Bacterial strains and plasmids used in this study are listed in Table 3.

Creation and analysis of a bank of nisin A ring-B derivatives

| 394 | transformants for the randomised P9XG10X bank. Isolated colonies were inoculated into 96-well           |
|-----|---|
| 395 | plates containing GM17 $\text{Cm}^{10}$ , incubated overnight and stored at -20°C after addition of 80% |
| 396 | glycerol. Deferred antagonism assays were performed by replicating strains on GM17 agar plates          |
| 397 | and allowing them to grow overnight before overlaying with GM17 agar (0.75% w/v agar)                   |
| 398 | seeded with the L. lactis HP indicator strain. Induction assays were carried out by replicating         |
| 399 | strains from each 96 well plate into a fresh 96 well plate containing GM17 broth pre-inoculated         |
| 400 | with L. lactis NZ9000 pNZ8150gfp+, in which GFP acts as a reporter of expression from a nisin           |
| 401 | inducible promoter (24). Induction of GFP was monitored over 20 hours in terms of relative              |
| 402 | fluorescence units (RFU) using a TECAN Genios Fluorescence, Absorbance and Luminescence                 |
| 403 | Reader using excitation and emission spectra of 485nm and 535nm, respectively.                          |
|     |   |

# 405 MALDI TOF Mass Spectrometry

| 406 | For Colony Mass Spectrometry (CMS), bacterial colonies of P9X and G10X mutants were           |
|-----|---|
| 407 | collected with sterile plastic loops and mixed with 50 $\mu$ L of 70% IPA containing 0.1%     |
| 408 | Trifluoroacetic acid (TFA). The suspension was vortexed, the cells centrifuged in a benchtop  |
| 409 | centrifuge at 8260 g for 2 min and the supernatant was removed for analysis. For MALDI TOF    |
| 410 | Mass Spectrometry of nisin M cell free supernatant (CFS) was purified prepared as follows; a  |
| 411 | 1% inoculum of nisin mutant producing strains were grown overnight in 50 mL clarified TY      |
| 412 | broth and incubated overnight at 30°C. Following incubation cells were centrifuged at 5000rpm |
| 413 | for 20 mins at 4°C. Cell free supernatant (CFS) was removed and passed through a 1 g (6 mL)   |
| 414 | Strata C-18 E column (Phenomenex) pre-equilibrated with 6 mL methanol (Fisher Scientific,     |
| 415 | UK) and 6 mL HPLC grade $H_2O$ . The column was washed with 12 mL 30% ethanol and nisin       |
| 416 | eluted using 5 mL 70% isopropanol – 0.1% TFA. Mass Spectrometry in all cases was performed    |

Applied and Environmental Microbiology

AEM

417

| 417 | with an Axima 101 MAEDI 101 mass spectrometer (Similadza Dioteen, Materiester, CK). A                       |
|-----|---|
| 418 | $0.5 \ \mu L$ aliquot of matrix solution (alpha-cyano-4-hydroxycinnamic acid (CHCA), $10 \ mg \ mL^{-1}$ in |
| 419 | 50% acetonitrile-0.1% (v/v) TFA) was placed onto the target and left for 1-2 min before being               |
| 420 | removed. The residual solution was then air dried and the sample solution (re-suspended                     |
| 421 | lyophilised powder or CMS supernatant) was positioned onto the pre-coated sample spot. Matrix               |
| 422 | solution (0.5 $\mu$ L) was added to the sample and allowed to air-dry. The sample was subsequently          |
| 423 | analysed in a positive-ion linear mode.   |
| 424 |   |
| 425 | Purification of nisin A and nisin M   |
| 426 | Purifications of nisin A and variant, nisin M were carried out as per a previously employed (33)            |
| 427 | with modifications. Briefly, overnight cultures of L. lactis NZ9800 pDF05nisM (APC3920)                     |
| 428 | and L. lactis NZ9700 were inoculated at 0.5% into separate purified tryptone-yeast extract (TY)             |
| 429 | broth (2 $\times$ 900 mL) supplemented with 20% glucose and 20% $\beta$ -glycerophosphate, and incubated    |
| 430 | at 30°C overnight. Following incubation, the cultures were centrifuged at 6500g at 4°C for 15               |
| 431 | min. The supernatant was passed through a column containing $\sim$ 70g Amberlite XAD-16 beads               |
| 432 | and subsequently washed with 500 mL of 30% ethanol. The nisin was eluted from the column                    |
| 433 | using 70% isopropanol containing 0.1% trifluoroacetic acid (TFA). Simultaneously, bacterial                 |
| 434 | cell pellets were resuspended in 300 mL 70% isopropanol – 0.1% TFA and stirred at room                      |
| 435 | temperature for 3 h. This cell suspension was then centrifuged at 5000g at 4°C for 10 min and               |
| 436 | the supernatant was retained. The column eluant was pooled with the post-centrifugation                     |
| 437 | supernatant and isopropanol evaporated using a rotary evaporator (BÜCHI Rotavapor R-205,                    |
| 438 | Switzerland). The pH of the sample was adjusted to pH 4.0 and was subsequently passed through               |
|     |   |

with an Axima TOF<sup>2</sup> MALDI TOF mass spectrometer (Shimadzu Biotech, Manchester, UK). A

439 a 10 g (60 mL) Strata C-18 E column (Phenomenex) pre-equilibrated with 60 mL methanol

Applied and Environmental Microbiology

AEM

Applied and Environmental Microbiology

440

| 441 | was eluted from the column using 60 ml 70% isopropanol – $0.1\%$ TFA. For HPLC purification          |
|-----|--|
| 442 | 12 mL volumes were concentrated to a volume of 2 mL by rotary evaporation and applied to a           |
| 443 | Phenomenex C12 reverse-phase (RP-HPLC) column (Jupiter 4 $\mu m$ proteo 90 Å, 250 mm $\times$ 10.0   |
| 444 | mm, 4 $\mu$ m) previously equilibrated with 25% acetonitrile-0.1% TFA. Nisin was eluted via a        |
| 445 | gradient of 25–50% acetonitrile-0.1% TFA that was developed from 10–40 min at a flow rate of         |
| 446 | 3.2 mL min <sup>-1</sup> . Nisin containing fractions were pooled and acetonitrile removed by rotary |
| 447 | evaporation. The purified peptides were lyophilised and stored at -20°C.                             |
| 448 |  |
| 449 | Minimum Inhibitory Concentration (MIC) Assays  |
| 445 | Winning minorory concentration (Wite) Assays   |
| 450 | MIC's were also carried out on strains into which the NICE system was reported to have been          |
| 451 | introduced including, Lactobacillus plantarum (Lb. plantarum) and Lactobacillus brevis (Lb.          |
| 452 | brevis) in order to determine the potential of nisin M as an alternative to nisin A in the NICE      |
| 453 | system.  |
| 454 | Minimum inhibitory concentration determinations for strains were carried out in triplicate in 96     |
| 455 | well microtitre plates (Sarstedt) as described previously (34). Plates were pre-treated with bovine  |
| 456 | serum albumin (BSA) prior to addition of the peptides. Briefly, to each well of the microtitre       |
| 457 | plate 200 $\mu$ L of phosphate buffered saline (PBS) containing 1% (w/v) bovine serum albumin        |
| 458 | (BSA) was added and incubated at 37°C for 30 min. The wells were washed with 200 $\mu L$ PBS         |
| 459 | and allowed to dry. Target strains, L. lactis spp. cremoris HP, L. lactis NZ9000 pNZ8150gfp+         |
| 460 | were grown overnight in M17 broth (Sigma) supplemented with glucose (0.5%) at 30°C. Lb.              |
| 461 | plantarum and Lb. brevis were grown overnight in MRS broth (Oxoid) at 30°C. Strains were             |

(Fisher Scientific, UK) and 60 mL HPLC grade H<sub>2</sub>O. After applying 120 mL 30% ethanol, nisin

| 462 | sub-cultured into fresh broth and allowed to grow to an $OD_{600}$ of ~0.5, diluted to a final        |
|-----|---|
| 463 | concentration of $10^5$ cfu mL <sup>-1</sup> in a volume of 0.2 mL. Nisin A and nisin M peptides were |
| 464 | adjusted to a 750 nM starting concentration and 2-fold serial dilutions of each peptide was added     |
| 465 | to the target strain. After incubation for 16 h at 30°C the MIC was read as the lowest peptide        |
| 466 | concentration causing inhibition of visible growth.   |

Comparison of nisin A and nisin M induction capacity using beta-galactosidase activity

467

468

| 469 | $\beta$ -galactosidase activity assay was performed as previously employed (35) with modifications.           |
|-----|---|
| 470 | Cultures of <i>L. lactis</i> NZ9000 pPTPL $\beta gal$ + were inoculated in M17 broth (Sigma), supplemented    |
| 471 | with glucose at 0.5% (GM17) and tetracycline (10 $\mu$ g mL <sup>-1</sup> ), and incubated at 30°C overnight. |
| 472 | Following incubation, a 1% inoculum of each replicate was sub-cultured into fresh GM17                        |
| 473 | medium and incubated at 30°C until an $OD_{600}$ of 0.2-0.3 was reached. Cells were then treated              |
| 474 | separately with nisin A and nisin M purified peptides to a final concentration of 10 ng mL <sup>-1</sup> .    |
| 475 | Every hour 1 mL samples of each test were transferred to an eppendorf and centrifuged at 13,000               |
| 476 | rpm for 2 minutes (Sorvall Legend Micro 17 centrifuge, Thermo Scientific) to harvest cells.                   |
| 477 | Cells were re-suspended in 1 mL lacZ buffer and 0.5 mL of this was treated with 12.5 $\mu$ L of               |
| 478 | 0.1% SDS and 25 $\mu$ L of chloroform and incubated at 30°C for 5 minutes to dissolve cell                    |
| 479 | membranes. Following incubation 100 $\mu$ L of 2-Nitrophenyl- $\beta$ -D-galactopyranoside (ONPG) (4          |
| 480 | mg mL <sup>-1</sup> ) (Sigma-Aldrich) was added to each sample and incubated at 37°C until a yellow colour    |
| 481 | developed. To stop the reaction samples were treated with 250 $\mu$ L of a 1 M sodium carbonate               |
| 482 | solution and centrifuged at 8000rpm for 5 minutes (Thermo Scientific). Absorbance readings of                 |
| 483 | supernatant were read at $OD_{420}$ and $OD_{550}$ (SpectraMax M3 spectrophotometer, Molecular                |

484 Devices, Sunnyvale, California, USA). Measurement of β-galactosidase activity of samples was 485 calculated as  $1000 \times (OD_{420} - [1.75 \times OD_{550}])/(t \times v \times OD_{600})$  as previously described (16).

486

Assessment of purified nisin A and nisin M induction capacity using a green fluorescent proteinreporter system.

Induction assays were performed previously described (24) with modifications. Briefly, cultures 489 of L. lactis NZ9000 pNZ8150gfp + were inoculated in M17 broth (Sigma), supplemented with 490 glucose at 0.5% (GM17) with chloramphenicol (10  $\mu$ g mL<sup>-1</sup>) and incubated at 30°C overnight. 491 492 Following incubation, a 1% inoculum of each replicate was sub-cultured into fresh GM17 493 medium and incubated at 30°C until an  $OD_{600}$  of ~0.5 was reached. Cells were then diluted to a final concentration of 10<sup>5</sup> cfu mL<sup>-1</sup> and treated with nisin A and nisin M at final concentrations of 494 10 ng mL<sup>-1</sup>, 50 ng mL<sup>-1</sup>, 100 ng mL<sup>-1</sup> and 300 ng mL<sup>-1</sup>. Subsequently, 2 mL was transferred to 495 black, 24 well microtitre plates (PerkinElmer) for induction and 200 µL into a 96 well plate 496 497 (Sarstedt) for absorbance readings. Fluorescence was detected using a SpectraMax M3 498 spectrophotometer (Molecular Devices, Sunnyvale, California, USA) where excitation and 499 emission parameters were set to 485nm and 528nm respectively for fluorescence, while 500 absorbance readings were taken at OD<sub>595</sub> using a Multiskan FC microplate photometer v1.01.14 501 (Thermo Scientific, Waltham, Massachusetts, USA). Baseline absorbance of un-cultured GM17 502 was subtracted from the fluorescence and absorbance readings of all test samples using SoftMax 503 Pro v6.3 and SkanIt RE v4.1 software, respectively. Fluorescence was reported as relative light units (RLU) and absorbance as OD<sub>595nm</sub>. Tests were carried out in triplicate. 504

#### 509 Statistical analysis

510 Statistical analysis was carried out with SPSS Statistics v2. A test of normality was performed to 511 determine data for each test was normally distributed. For normally distributed data a Repeated Measures ANOVA was performed. For data not normally distributed a Levene's test of 512 homogeneity was performed, where if equal variances were assumed the Repeated Measures 513 514 ANOVA was carried out; and if equal variances were not assumed the non-parametric Friedman 515 test was performed to determine if differences between the two nisin variants induction capacity, and between the growth of the strains when induced with the peptides at higher concentrations 516 517 compared to an un-induced control were significant. For ANOVA/Friedman's results with a significant difference between groups ( $P \le 0.05$ ) a post hoc test was performed. Post hoc tests for 518 519 normally distributed/equal variances assumed samples was the Bonferroni test, and for non-520 normally distributed/equal variances not assumed samples Dunnett's T3 test was performed. The 521 significance threshold for all ANOVA's and non-parametric tests performed was set at .05. 522
