### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

# Three-dimensional Self-assembled Columnar Arrays of AlInP Quantum Wires for Polarized Micron-sized Amber Light Emitting Diodes

KEYWORDS: Self-assembled nanowires, columnar nanowire, yellow LED, polarized LED

*A three-dimensional ordered and self-organized semiconductor system emitting highly-polarized light in the yellow-orange visible range (580-650 nm) is presented, comprising self-assembled in-plane AlInP wires vertically stacked in regularly-spaced columns. More than 200 wires per column without detectable defect formation could be stacked. Theoretical simulations and temperature-dependent photoluminescence provided a benchmark to engineer multilayered structures showing internal quantum efficiency at room temperature larger than comparable quantum wells emitting at similar wavelengths. Finally, proof-of-concept light emitting diodes (LED) showed a high degree of light polarization and lower surface parasitic currents than comparable quantum well LEDs, providing an interesting perspective for high-efficiency polarized yellow-orange light emitting devices.*

1  
2  
3 Light emitting diodes (LEDs) are currently driving innovation in many technological areas,  
4 such as displays for TV/monitors, mobiles and laptops, lighting and automotive, optical  
5 interconnections, logic and sensing.<sup>1-4</sup> A key factor for success is the ability to produce light  
6 with high efficiency and with a very small footprint, i.e. fundamental properties compatible  
7 with the demanding requirements of compactness and integrability. As a consequence,  
8 considerable effort has been dedicated to the investigation of novel materials and designs for  
9 LED devices, aiming to improve efficiency, spectral properties and to add integrated  
10 functionalities.<sup>5-14</sup>

11  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21 However, some fundamental issues in light emitting diode technology are still outstanding.  
22 For instance, semiconductor-based III-V LEDs show a well-known drop in efficiency at  
23 wavelengths in the range of 550-640 nm (yellow-red optical band of the spectrum) in both  
24 nitride-based and phosphorus-based compounds.<sup>15</sup> In III-P compounds this is linked to poor  
25 electron confinement (related to the direct-to-indirect bandgap transition for Al:Ga ratio  
26 above ~53:47% in AlGaInP lattice-matched to GaAs,<sup>15</sup> which result in a severe reduction in  
27 the radiative recombination efficiency), while in InGaN materials the increasing In content,  
28 required to shift the emission from blue towards the yellow, introduces a larger number of  
29 structural defects, segregation and strong quantum mechanical Stark effects that seem  
30 unavoidable detrimental factors for optical properties.<sup>16-19</sup> Moreover, traditional quantum  
31 well LEDs can show a strong reduction in current-to-light conversion efficiency due to non-  
32 radiative recombination paths created by surface states (particularly relevant in LEDs in the  
33 micron size range), a very relevant limiting factor for truly microLED technology  
34 implementation. It should also be added that polarized light emission, critically required in a  
35 variety of applications such as LCD screens and environmental lighting,<sup>20-22</sup> is presently  
36 achieved only by additional structures such as gratings, filters and plasmonic nanostructures

2  
3 that increase the complexity of the device fabrication and reduce the external quantum  
4 efficiency.<sup>23-30</sup>  
5  
6  
7

8 A viable approach able to mitigate these outstanding issues could be the exploitation of  
9 carrier confinement in low dimensional nanostructures. For instance, epitaxial growth has  
10 been used to self-assemble high density and high crystal quality quantum dots (QDs)  
11 providing high temperature stability and low threshold currents in lasers and LEDs.<sup>31-33</sup>  
12 Nevertheless this is a paradigm that critically requires no (defect-related) lattice relaxation.  
13 AlGaInP alloys for red emitters do not offer issues in terms of lattice relaxation, as lattice-  
14 matching to GaAs can be constantly maintained while varying the Al content to shift the  
15 emission from red (650 nm for simple InGaP lattice-matched to GaAs) to yellow, maintaining  
16 high crystal quality without any polar crystallographic direction. We observe, on the other  
17 hand, that although the quasi 0-dimensionality of QDs allows maximizing the carrier  
18 quantum confinement, polarized light for surface emission cannot be directly produced due to  
19 a generally high symmetry of the crystallographic structures, as it is also the case in the  
20 traditionally exploited quantum wells.

35  
36

37 In this regard, the one-dimensionality of wire-like nanostructures would allow the unique  
38 coexistence of better carrier confinement and spontaneous polarized emission.<sup>34</sup> However,  
39 reliable and scalable methods to grow embedded self-assembled wires without pre-patterned  
40 templates (such as V-grooves),<sup>35, 36</sup> and with a design optimized for yellow-orange light  
41 emission are, to date, missing.  
42  
43  
44  
45  
46  
47  
48

49 Here we present a reproducible growth process to realize ordered self-assembled  
50 multilayered in-plane AlInP/AlGaInP quantum wires (SMWRs) grown on a GaAs substrate.  
51 The wires, with lateral size of ~10-25 nm, center-to-center spacing in the growth plane of ~50  
52 nm and a few microns in length, can be organized in vertical columns of up to 200 wires per  
53

3 column, and show light emission in the yellow-orange visible range (580-650 nm).  
4  
5 Temperature-dependent photoluminescence spectroscopy alongside a 8-band **k·p** model  
6  
7 simulations were exploited to unveil the fundamental physical processes in light production,  
8  
9 including the influence of escape processes and band alignments, and to estimate the internal  
10  
11 quantum efficiency (IQE).  
12  
13

14  
15 We also show that the IQE of a 100 layer SMWR structure can be critically improved by  
16  
17 adding a quantum well (QW) coupled to the SMWR system (QW-SMWR), functioning as a  
18  
19 carrier injector. When compared to a (comparable, but by no means optimized) AlGaInP five  
20  
21 QW structure, the IQE of the QW-SMWR hybrid system outperformed the QW structure in  
22  
23 the entire range of temperature explored (4-300 K), exhibiting up to one order of magnitude  
24  
25 higher internal quantum efficiency (at 100 K). Finally, prototype LED devices were  
26  
27 characterized showing low turn-on voltage, lower surface recombination currents compared  
28  
29 to QW LEDs and highly polarized in-plane light emission. The results obtained from the  
30  
31 QW-SMWR system show great potential in terms of design flexibility and emission  
32  
33 efficiency, opening up interesting perspectives towards development of cryogenic and room  
34  
35 temperature optoelectronic devices.  
36  
37  
38

39  
40 All epitaxial samples discussed were grown in a high purity MOVPE<sup>37-39</sup> commercial  
41  
42 horizontal reactor (AIX 200) at low pressure (80 mbar) with purified N<sub>2</sub> as carrier gas. The  
43  
44 precursors were trimethylindium (TMIn), trimethylgallium (TMGa), trimethylaluminium  
45  
46 (TMAI), diethylzinc (DEZn) arsine (AsH<sub>3</sub>), phosphine (PH<sub>3</sub>) and disilane (Si<sub>2</sub>H<sub>6</sub>). The  
47  
48 samples' designs consisted in 100 nm Al<sub>0.75</sub>Ga<sub>0.25</sub>As, 100 nm (Al<sub>0.8</sub>Ga<sub>0.2</sub>)<sub>0.52</sub>In<sub>0.48</sub>P followed  
49  
50 by alternating layers of (Al<sub>0.6</sub>Ga<sub>0.4</sub>)<sub>0.52</sub>In<sub>0.48</sub>P barrier and of Al<sub>x</sub>In<sub>1-x</sub>P (0.15<x<0.30) with  
51  
52 nominal thickness of 3 nm and 0.4 nm respectively. Variation to this design will be described  
53  
54 in the text. All growth temperatures (T) quoted have been estimated by emissivity corrected  
55

2  
3 pyrometry. All samples had a homoepitaxial GaAs 100 nm thick buffer grown prior to the  
4 described structure and were capped with 200 nm of  $(\text{Al}_{0.8}\text{Ga}_{0.2})_{0.52}\text{In}_{0.48}\text{P}$ . Growth conditions  
5 for the AlGaInP layers were: V/III ratio  $\sim 630$ , growth rate  $\sim 0.4$  nm/s; growth conditions for  
6 the AlInP layers were: V/III ratio 290, growth rate 0.3 nm/s; samples were grown at growth T  
7 of  $720^\circ\text{C}$  on semi-insulating (100)  $6^\circ \pm 0.02^\circ$  off towards [111] A (unless stated otherwise).  
8 The LED devices were grown on a n-doped GaAs substrate  $6^\circ \pm 0.02^\circ$  off towards (111) A.  
9 The structure consisted in 100 nm  $\text{Al}_{0.75}\text{Ga}_{0.25}\text{As}:\text{Si}$  ( $n\sim 10^{18}\text{cm}^{-3}$ ), 100 nm  
10  $(\text{Al}_{0.8}\text{Ga}_{0.2})_{0.52}\text{In}_{0.48}\text{P}:\text{Si}$  ( $n\sim 10^{18}\text{cm}^{-3}$ ) followed by alternating layers of  $\text{Al}_x\text{In}_{1-x}\text{P}$  and of  
11  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$ , as previously described. All samples had a homoepitaxial GaAs:Si  
12 ( $n\sim 10^{18}\text{cm}^{-3}$ ) 100 nm thick buffer grown prior to the described structure and were finalized  
13 with 100 nm of  $(\text{Al}_{0.8}\text{Ga}_{0.2})_{0.52}\text{In}_{0.48}\text{P}$ , 100 nm of  $(\text{Al}_{0.8}\text{Ga}_{0.2})_{0.52}\text{In}_{0.48}\text{P}:\text{Zn}$  ( $n\sim 10^{18}\text{cm}^{-3}$ ), 100  
14 nm AlInP:Zn ( $n\sim 10^{18}\text{cm}^{-3}$ ), 10 nm InGaP:Zn ( $n\sim 10^{18}\text{cm}^{-3}$ ) and 10 nm of GaAs:Zn ( $n\sim 10^{18}\text{cm}^{-3}$ ).  
15 Standard optical lithography, dry-etch and deposition of Ti/Pt/Au (20/30/200 nm) metal  
16 contact on the p-side were used to fabricate the LED devices (further details in the  
17 Supporting Information (SI)).

**Figure 1:** AFM images (a) signal amplitude and (b) reconstructed 3D height image of a single un-capped layer of 0.4 nm (nominal) of  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  grown on a  $6^\circ$  off GaAs substrate. (c) photoluminescence spectra (at 8K) of single capped  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}/(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  layer grown at 620 (light blue dots), 670 (blue dots), 720 (dark blue dots)  $^\circ\text{C}$ , respectively, compared to a sample in which  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  layers were grown at 720  $^\circ\text{C}$  and AlInP layers at 620  $^\circ\text{C}$  (red line). (d) Cross-section TEM of a SMWR with 8  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  layers separated by 10 nm  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  barriers.

Deposition of lattice-mismatched  $\text{Al}_x\text{In}_{1-x}\text{P}$  ( $0.15 < x < 0.30$ ) on  $(\text{Al}_y\text{Ga}_{1-y})_{0.52}\text{In}_{0.48}\text{P}$  ( $0.3 < y < 0.90$ ) lattice-matched to GaAs led to spontaneous self-assembled nanostructures via Stranski–Krastanov growth.<sup>40</sup> Although 3 monolayers (ML) of InP on  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  deposited at 620  $^\circ\text{C}$  resulted in well-defined semi-spherical dots, typically emitting around  $\sim 700$  nm (see figure S1 in SI), a significant blue-shifted emission can be achieved by Al

1  
2  
3 incorporation and reduction of the number of monolayers down to 1-2. Figure 1a-b shows the  
4 surface morphology of a single uncapped layer of 0.4 nm (nominal) of  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  (grown on  
5  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$ ) on a  $6^\circ$  off GaAs substrate). The thin layer of material deposited, while  
6 developing elongated features on the surface, did not allow to distinguish between quantum  
7 dot- or dash-like structures or what could be a simple step bunched surface organization as  
8 typically found for MOVPE grown III-V alloys; we note that AlGaInP alloys grown by  
9 MOVPE tend to show only very short range surface organization, unlikely their arsenide and  
10 InP counterparts.<sup>38, 41, 42</sup>

19  
20  
21 Photoluminescence investigations of samples capped with 200 nm of  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$   
22 showed that the InP “dot-like” emission was shifted towards shorter wavelengths, around 600  
23 nm. Figure 1c shows the PL spectra of three representative samples in which both the  
24  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  (0.4 nm) and  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  layers were grown at the same temperature  
25 (620, 670 and 720 °C, respectively) compared to a reference sample where the  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$   
26 layers were grown at 620 °C and the  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  layers at 720 °C. The  
27  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  emission showed a blue-shift with increasing growth temperature, as  
28 expected from the reduction of CuPt ordering<sup>43</sup> and also a reduction in intensity, possibly  
29 related to closer proximity to the direct-to-indirect bandgap transition. The increasing  
30 temperature also resulted in the  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  emission blue-shifting. The broad peak around 630  
31 nm at 620 °C became a narrow emission around 590 nm, suggesting reduced lateral  
32 dimensions and possibly more uniform sizes of the  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  nanostructures.

4 0.4 nm (nominal) of  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  separated by 3 nm (nominal) of  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  grown  
5 on a  $6^\circ$  off GaAs substrate. The surface appeared to have RMS below 1 nm and height  
6 variations in range of few hundreds of picometers along the wire. (b) Cross section TEM of a  
7 SMWR with 60 layers, including an  $(\text{Al}_{0.5}\text{Ga}_{0.5})_{0.52}\text{In}_{0.48}\text{P}$  QW on top of the SMWR (wire  
8 direction is perpendicular to the plane). (c) Enlargement of the pedestal of a SMWR column.  
9  
10  
11  
12  
13  
14  
15  
16  
17

18 The system morphology showed an interesting evolution with increasing number of layers  $l$   
19 when the  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  barrier was decreased down to 3 nm and  $l$  increased to more  
20 than  $\sim 20$ . The surface morphology of the un-capped sample (figure 2a), where 20  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$   
21 layers were stacked, and growth finished with the deposition of the last one (without capping  
22 layer), indicated the presence of wire-like ordering with length between 0.5-2  $\mu\text{m}$  and width  
23 around 25 nm elongated orthogonally to the substrate tilt direction. The corresponding TEM  
24 cross section perpendicular to the wire long axis in figures 2b-c shows a highly ordered  
25 system with vertical columns of  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  wires having a periodicity of around 25 nm.  
26 Notably, the self-organization in columns shows a long-range ordering of microns length  
27 (along the substrate tilt direction), as demonstrated by the low magnification TEM and SEM  
28 pictures showing column arrays without any observable structural defect (see figure S2 in SI).  
29 Moreover, focusing at the bottom of each column, one can observe a pedestal-like structure at  
30 the beginning of the column formation process. Indeed, the first stacked layers are much  
31 more disordered, in agreement with the AFM scan of a single layer, as shown in figure 1a-b.  
32 From the cross-section TEM picture, it can be inferred that the system takes around 20 layers  
33 in order to self-organize in regular spaced columns arising from the vertical correlation of the  
34 in-plane wire formation. We speculate that this organization is fundamentally driven by strain  
35 forces related to the large lattice mismatch between the  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  layer, which is

1  
2  
3 lattice-matched to GaAs, and the strained thin  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  layers.<sup>40</sup> It is also worth to note that  
4  
5 after the required  $\sim 20$  layers to reach an organized morphology, the resultant system is very  
6  
7 stable for a further increase of  $l$ , allowing growth of samples with up to  $l=200$ . We also  
8  
9 observed that multilayered structures resulted in very different morphologies on perfectly  
10  
11 oriented GaAs substrates, and, in general, it was not possible to grow 20 or more layers  
12  
13 without the appearance of evident structural relaxation and a resulting red-shift of the  
14  
15 emission above 700 nm. Accordingly, we speculate that the surface step (bunched)  
16  
17 organization in a  $6^\circ$  off GaAs substrate affects the  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  ad-atom incorporation and in-  
18  
19 plane ad-atom mobility and constitutes a key factor for the long-range self-organization of the  
20  
21  $\text{AlInP}$  wires (see SI).  
22  
23  
24

25 We finally observe that while the growth organization here seems unique to this material  
26  
27 system and has no obvious equivalent in the literature, vertical nanostructure organization has  
28  
29 been indeed reported several times in other systems. For early examples see references 44-46.

**Figure 3:** (a) 8 K photoluminescence spectrum of a SMWR with 60 layers, peaked at 580 nm. Insert highlights the weak  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  barrier emission around 545 nm. (b) Comparison between the photoluminescence spectra at room temperature of SMWRs with 8 (light blue line), 20 (blue line) and 60 (red line) layers. Notably, the 8 layer SMWR did not show any detectable emission at room temperature.

Figure 3a shows the photoluminescence spectrum at 8 K of a representative sample with  $l=60$ . The small peak around 545 nm can reasonably be attributed to the  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  barrier emission. The weak intensity of this peak was expected due to the indirect nature of the  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  bandgap ( $(\text{Al}_x\text{Ga}_{1-x})_{0.48}\text{In}_{0.52}\text{P}$  should show a direct-to-indirect transition at  $x\sim 0.53$ ). Interestingly, a further increase of the Al content, i.e. further increase of the indirect bandgap, decreased the  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  wire emission (see figure S3 in SI). Such a photoluminescence quenching was previously reported in AlGaAs and AlGaInP systems and

1  
2  
3 attributed to an increase of point defects with the Al content in AlGaInP.<sup>47</sup> On the other  
4  
5 hand, the stronger peak at 580 nm, tunable by varying the Al content in the AlInP compound,  
6  
7 is attributed to the “wire” emission. Moving from 8 K to room temperature the wire emission  
8  
9 was red-shifted by roughly 10-20 nm, comparable to the bandgap renormalization described  
10  
11 by the Varshni equation, and dropped by more than 2 orders of magnitude in intensity.  
12  
13

14  
15 Figure 3b compares the RT emission of three structures having 8, 20 and 60  
16  
17  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}/(\text{Al}_{0.4}\text{Ga}_{0.6})_{0.52}\text{In}_{0.48}\text{P}$  layers respectively. Although the SMWR with  $l=8$  did not  
18  
19 show any detectable emission at RT, a drastic increase in intensity by at least two orders of  
20  
21 magnitudes was observed when  $l$  was increased from 8 to 20, while a linear trend with the  
22  
23 layer number was found for  $l > 20$ . This is in agreement with the morphology evolution  
24  
25 described in figure 2, in which around 20 periods were required for self-assembled ordering  
26  
27 in the columnar nanowires to become established. We also noticed, since the morphology of a  
28  
29 multilayer structure with  $l > 20$  was very stable, that the room temperature intensity can be  
30  
31 improved by a simple proportional increase of the number  $l$  (this has been experimentally  
32  
33 verified up to  $l=200$ ).

**Figure 4:** (a) Temperature dependent normalized integrated intensity. Blue line indicates the data fit obtained with eq. 1. (b) Theoretical simulation of the expected band alignment in the growth plane in a 15 nm thick and 2.2 nm tall Al<sub>0.2</sub>In<sub>0.8</sub>P wire surrounded by (Al<sub>0.6</sub>Ga<sub>0.4</sub>)<sub>0.52</sub>In<sub>0.48</sub>P at 300 K, plotted along a line through the center of the wire, and perpendicular to the wire axis, and (c) plotted through the center of the wire along the growth direction. The solid lines depict the bulk band edges, and the dashed lines correspond to the ground confined states. The vertical and horizontal separation between wires is 1.2 nm and 25

1  
2  
3 nm, respectively.  
4  
5

6 The evolution of the IQE with temperature of a SMWR with  $l=60$  is presented in figure 4a.  
7  
8 The overall trend expected for an AlGaInP system is a decrease in emission intensity with  
9 increasing temperature, attributed to thermally activated escape of excitons from the (poorly)  
10 confined regions (wires here, wells in conventional red emitters) to the barriers and to  
11 subsequently non-radiative recombination processes.<sup>47, 48</sup> However, we observe that before  
12 the drop in intensity for  $T>100$  K the integrated intensity showed an anomalous increase,  
13 reaching its maximum around 50-60 K.<sup>49</sup> Moreover, a model based on a single escape process  
14 was not able to reproduce the data trend above that temperature (see SI).<sup>48</sup>  
15

17  
18  
19  
20  
21  
22  
23

24 In order to understand this behavior and get more insights into the system dynamics, we  
25 simulated the expected band structure of the  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}/(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  SMWR system  
26 (figure 4b-c), using an 8-band **k-p** model for the zone-center  $\Gamma$  states, a one-band model for  
27 each of the three X states, and ignoring the effects of substrate tilt on the calculated states.  
28 Details of the wire structure considered, and of further variations on wire structure are given  
29 in SI. The conduction band minimum in the  $(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  barrier is located, as  
30 expected, in the X valley. The 2.2% lattice mismatch between the  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}$  SMWR and the  
31 GaAs substrate results in a strain distribution across the SMWR and the surrounding barrier  
32 layers, causing a further reduction of the indirect band gap in the barrier by splitting the X  
33 states into  $X_{\perp}$  and  $X_{\parallel}$  (see SI), where  $X_{\perp}$  are the two X states in the growth plane, while  $X_{\parallel}$   
34 is the X state along the growth direction. The band alignment for  $l=60$  in figure 4b-c shows that  
35 the X states in the quantum wires act as a potential barrier, with the lowest X states in the  
36 barrier material. For the SMWR structure considered here, the lowest confined X state is in  
37 the  $X_{\perp}$  valley, although it is possible, e.g. by assuming a wider vertical separation between  
38 wires, to have the lowest confined X state in the  $X_{\parallel}$  valley. In either case, however, the X

1  
2  
3 states have larger electron effective mass compared to the  $\Gamma$  valley. Assuming the transition  
4  
5 of the  $\Gamma$ -like electrons in the quantum wire into the barrier X valley is the likely thermally  
6  
7 activated non-radiative pathway in this structure, we find that the potential barrier for direct  
8  
9 gap electrons is 10 – 40 meV, depending on exact structure assumed (40 meV in figure 4b-c).  
10  
11 On the other hand, heavy holes are confined much deeper in the wire, with the potential  
12  
13 barrier between 120 – 195 meV (53 and 178 meV in figure 4b-c respectively to the barrier  
14  
15 heavy-hole band edge). Our calculations also show that the variation of wire geometry, which  
16  
17 can be seen in figure 2, does not change the (ground state) transition energy significantly  
18  
19 enough to reproduce the width of the PL spectra, and it is likely that interdiffusion of Al and  
20  
21 Ga occurs between the wire and barrier during growth (see SI).  
22  
23  
24

25 Building on this analysis, we have used a simple model to describe the temperature  
26  
27 dependence of the emission intensity observed in figure 4a. Since the conduction band  
28  
29 minimum in AlGaInP is at the X point in reciprocal space, the carrier migration rate from the  
30  
31 barriers into the wires is reduced at low temperature, due to the low number of phonons  
32  
33 available. However, the electron-phonon scattering probability increases approximately  
34  
35 quadratically with temperature, thus allowing excited carriers in the barriers to diffuse into  
36  
37 the wires and enhance the wire emission intensity. For temperatures higher than 50-60 K,  
38  
39 confined carriers can leak out from the wire. In particular, electrons should be the first to  
40  
41 have enough thermal energy to escape, based on the asymmetric carrier confinement energies  
42  
43 derived from theory. This process should be followed by a similar thermally activated  
44  
45 emission of holes at higher temperatures. If so, the thermally activated migration of carriers  
46  
47 from the wire to the barriers and the availability of non-radiative recombination paths outside  
48  
49 the wire should be considered the dominant mechanism behind the loss of intensity at room  
50  
51 temperature.  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 According to this, we can estimate the formal behavior of temperature dependency of the  
4  
5 integrated intensity  $I(T)$  as (see SI)

$$6$$

$$7$$

$$8$$

$$9 \quad I(T) \propto \frac{1}{1 + \tau_r(T) \left( \frac{1}{\tau_{es}^e(T)} + \frac{1}{\tau_{es}^h(T)} - \frac{1}{\tau_{in}(T)} \right)}$$

$$10$$

$$11$$

12  
13 where  $\tau_r$  is the radiative lifetime,  $\tau_{es}^e$  and  $\tau_{es}^h$  the escape time constant for electron and holes  
14  
15 respectively and  $\tau_{in}$  the time constant for carrier injection from the barriers to the wires. The  
16  
17 variation of the radiative lifetime with temperature can be described as  $\tau_r(T) \sim \sqrt{T}$  for a wire  
18  
19 ( $\tau_r(T) \sim T$  in a well), with  $\tau_{es}^{e/h}(T) \sim e^{E_{act}/kT}$  and  $\tau_{in}(T) \sim T^{-2}$ .<sup>50, 51</sup>

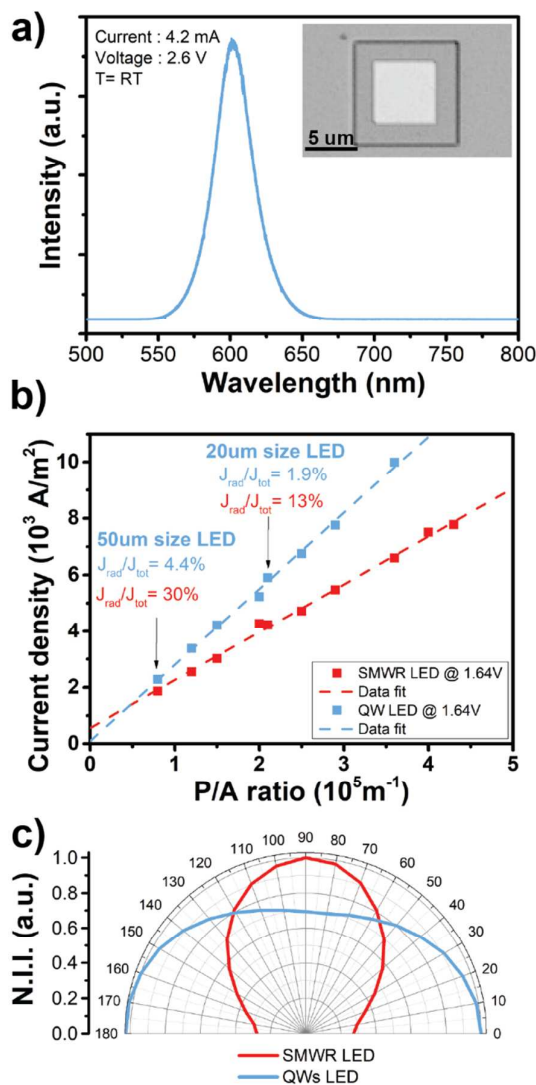

20  
21  
22  
23 The data fit showed in figure 4a reproduces well the data across the whole range of  
24  
25 temperature. In particular the fit provides  $\sim 20$  meV and  $\sim 120$  meV as activation energies for  
26  
27 electrons and holes respectively, in reasonable agreement with the theory. It should be noted  
28  
29 that according to theoretical predictions electron confinement in  $(Al_{0.3}Ga_{0.7})_{0.52}In_{0.48}P$  QWs  
30  
31 (emitting at the same wavelength) is expected to be larger, potentially leading to a higher IQE  
32  
33 at high temperatures.  
34  
35

**Figure 5:** (a) Comparison between the temperature dependent normalized integrated intensities of a SMWR with 60 layers (light blue), a SMWR with 100 layers (blue), a QW-SMWR with 60 layers (dark blue) and a 5 QW  $(\text{Al}_{0.3}\text{Ga}_{0.7})_{0.52}\text{In}_{0.48}\text{P}/(\text{Al}_{0.4}\text{Ga}_{0.6})_{0.52}\text{In}_{0.48}\text{P}$  structure (red). (b) Schematic illustration of the band alignment in the hybrid QW-SMWR system in which the QW is used to inject carriers into the SMWR system.

In order to investigate this aspect, figure 5a compares the temperature-dependent IQE of SMWRs with  $l=60$  and  $l=100$ , respectively, and a 5QW  $(\text{Al}_{0.3}\text{Ga}_{0.7})_{0.52}\text{In}_{0.48}\text{P}/(\text{Al}_{0.4}\text{Ga}_{0.6})_{0.52}\text{In}_{0.48}\text{P}$  structure emitting at similar wavelength (the number of QWs and their thickness has been designed to sum up to give approximately the same amount of active material deposited as in our wire structures with 100 layers, i.e. with a comparable overall nominal thickness of the emitting layers). We assume the  $\sim 0$  K IQE to be near unity as is custom in these cases. While for  $T < 150$  K the SMWR IQE is larger than the that of the QW structure up to 1 order of magnitude (at  $T=100$  K), at RT the QW structure IQE exceeds that of the SMWRs by more than a factor of 2.

1  
2  
3 However, a much larger improvement in the room-temperature efficiency of our structures  
4 can be obtained in a hybrid system in which a single quantum well is coupled to the SMWR  
5 system. In this scheme of work, depicted in figure 5b, the additional  $(\text{Al}_{0.5}\text{Ga}_{0.5})_{0.52}\text{In}_{0.48}\text{P}$   
6 quantum well, having a bandgap slightly larger than the wires (i.e. not contributing to the  
7 wire emission photoluminescence), can be used as a reservoir to inject carriers into the wires,  
8 and partially compensate the thermally activated quenching of the emission.<sup>52</sup> The IQE of the  
9 resultant hybrid device, containing just 60 layers (just over half that of the SMWRs shown by  
10 the dark blue dots in figure 5a), showed more than one order of magnitude higher efficiency  
11 compared to the system without a QW, and exceeds the efficiency of the 5QW  
12  $(\text{Al}_{0.3}\text{Ga}_{0.7})_{0.52}\text{In}_{0.48}\text{P}/(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  structure over the full temperature range. We also  
13 noticed that a minor improvement in the overall efficiency was obtained by increasing Al  
14 content in AlGaInP barriers before and after the multilayer structure from  
15  $(\text{Al}_{0.6}\text{Ga}_{0.2})_{0.52}\text{In}_{0.48}\text{P}$  to  $(\text{Al}_{0.8}\text{Ga}_{0.2})_{0.52}\text{In}_{0.48}\text{P}$  and by adding some strain to these barriers (see  
16 SI). This result demonstrates that the SMWR structure can be engineered not only to achieve  
17 a specific target wavelength, but also to improve red emitter efficiency by structural design.

**Figure 6:** (a) Electroluminescence spectrum of a representative SMWR LED. Inset shows an optical image of the measured device. (b) Plot of current density versus Perimeter/Area (P/A) ratio, demonstrating a larger contribution of the surface current to the total current in a 5QW  $(\text{Al}_{0.3}\text{Ga}_{0.7})_{0.52}\text{In}_{0.48}\text{P}/(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  LED than in a SMWR LED. No significant spectral shift was observed in these current intervals (c) A normalized polar plot of the integrated intensity of linearly polarized light as a function of analyzer's angle. The light was collected from top-view from both LED devices.

1  
2  
3  
4  
5  
6  
7  
8 To test the feasibility of higher efficiency light emitting electrical devices, a prototype  
9 SMWR microLED device (structure details in SI), was compared to a similarly processed  
10 5QW  $(\text{Al}_{0.3}\text{Ga}_{0.7})_{0.52}\text{In}_{0.48}\text{P}/(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  LED. A representative electroluminescence  
11  
12 spectrum of a SMWR LED device indicated an optical emission peaked at 610 nm (at room  
13  
14 temperature), in agreement with the photoluminescence spectrum of the equivalent SMWR  
15  
16 structure and showed a turn on voltage of  $\sim 1.6$  V corresponding to a current density of  $\sim 0.1$   
17  
18  $\text{A}/\text{cm}^2$ . Similar values were observed for the QW LED, indicating that the low current density  
19  
20 required should be ascribed to the current-spreading layer design rather than the material  
21  
22 structure. Investigation of LED devices with comparable surface area but different perimeters  
23  
24 unveiled important differences in the surface current contribution for the two types of LEDs.  
25  
26 In a first approximation, the total current density injected into the LED can be described by<sup>53</sup>  
27  
28  
29  
30  
31

$$J_{TOT} = J_{bulk} + \sigma_{surf} \frac{P}{A}$$

32  
33 where  $J_{bulk}$  is the current density flowing through the bulk of the material,  $\sigma_{surf}$  (A/m) the  
34  
35 surface current per unit length of perimeter P and A the area of the LED, respectively.  
36  
37 Assuming that the carriers flowing through the surface do not recombine radiatively, and the  
38  
39 emission intensity is only proportional to  $J_{bulk}$ , the percentage of the injected current  
40  
41  $J_{bulk}/J_{TOT}$  that contributes to the radiative emission can be inferred from the linear fit of the  
42  
43 data. In particular, two different trends for the QWs and the SMWRs LEDs were observed. In  
44  
45 both devices only a small fraction of the injected current was actually passing through the  
46  
47 bulk of the material. In the  $50 \times 50 \mu\text{m}^2$  QW LED only 4.4 % of the total current is  
48  
49 contributing to the emission, with this value decreasing to 1.9 % in a  $20 \times 20 \mu\text{m}^2$  device. On  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 the other hand, the value of  $J_{bulk}/J_{TOT}$  in the SMWR LED was found to be 30 % and 13 %  
4  
5 for the  $50 \times 50 \mu\text{m}^2$  and  $20 \times 20 \mu\text{m}^2$  device, respectively, almost one order of magnitude larger.  
6  
7 The reduction of the surface leakage current was further supported by a reduction in the  
8  
9 current spreading (see SI) in the SMWR LED. In fact, the higher degree of space  
10  
11 confinement and potential fluctuations experienced by carriers in the wires, compared to that  
12  
13 in the QWs, reduces the carrier diffusion towards the LED surface before recombination.  
14  
15 This therefore suggests that higher current-to-light conversion efficiency and a LED size  
16  
17 reduction without any loss in efficiency are achievable in QW-SMWRs.  
18  
19  
20

21 An important additional benefit of SMWR LEDs is that their spontaneous light emission is  
22  
23 polarized predominantly along the wire main axis. Figure 6c shows the normalized integrated  
24  
25 intensity (NII) of linearly polarized light (filtered for polarization as described in SI) versus  
26  
27 the sample rotation angle for the SMWR and QW LEDs. The QW LED showed only a weak  
28  
29 sign (around 30 %, for definition see SI) of polarization along the substrate tilt direction,  
30  
31 indicating that the tilted GaAs substrate might affect the QW morphology or introduce  
32  
33 residual strain, resulting in a low degree of polarization. On the other hand, the wires  
34  
35 possessed strong emission anisotropy, with almost 80 % of the emitted light polarized along  
36  
37 the wire main axis, i.e. perpendicular to the substrate tilt direction, making them extremely  
38  
39 interesting for modern display/augmented reality (and similar) applications. It should be  
40  
41 noted also that the presence of a large metal contact covering more than 50 % of the LED top  
42  
43 surface reduced the amount of direct light that could be collected by the optical setup;  
44  
45 therefore we expect that the degree of polarization could have been reduced in our  
46  
47 measurements by scattered light from the sidewalls of the LED.  
48  
49  
50  
51

52 In conclusion, we presented a novel multilayer structure comprising self-assembled  
53  
54 columns of AlInP wires with tunable emission between 580 and 650 nm. The growth  
55  
56  
57  
58  
59  
60

1  
2  
3 condition and morphology was investigated and optimized, resulting in a reliable method to  
4 growth a large number of  $\text{Al}_{0.2}\text{In}_{0.8}\text{P}/(\text{Al}_{0.6}\text{Ga}_{0.4})_{0.52}\text{In}_{0.48}\text{P}$  layers at high temperature (720  
5 °C). The structure design was engineered to maximize the efficiency by optimizing AlInP and  
6 AlGaInP layer thicknesses, growth temperatures and Al content in the barriers. A qualitative  
7 physical model based on theoretical simulations was proposed and demonstrated capable to  
8 describe satisfactorily the SMWR temperature-dependent photoluminescence. The IQE was  
9 investigated and compared to a 5QW AlGaInP sample and to a QW-SMWR sample,  
10 demonstrating that adding a QW coupled to the SMWR system boosts by more than one  
11 order of magnitude the IQE, outperforming the AlGaInP QWs. Finally, investigation of the  
12 QW-SMWR microLED prototype indicated further advantages over the traditional QW LED  
13 in the reduced surface parasitic current and in the emission of strongly polarized light.

## SUPPORTING INFORMATION

Additional details and Supplementary Figures S1-S6.

## ACKNOWLEDGMENT

This research was enabled by Science Foundation Ireland under the IPIC award 12/RC/2276, grant 10/IN.1/I3000, 15/IA/2864 and the Irish Research Council under grant EPSPG/2014/35.

We thank Kevin Thomas for the MOVPE support.
