(read before the Society, 1st May 2014)

Abstract: This paper presents a new approach to measuring and understanding the activities of the tourism industries in Ireland. Using structural business statistics and administrative registers a new set of static and dynamic supply-side indicators are developed at both national and sub-national level. These indicators not only complement and expand the suite of tourism indicators already available but also offer a practical approach to filling a gap in the UNWTO – 2008 International Recommendations on Tourism Statistics.

Keywords: registers, tourism dependency ratios, International Recommendations on Tourism Statistics

JEL Classifications: L83, C10, C46

INTRODUCTION

Tourism activity is a complex, demand driven, phenomena. The tourism sector, as defined by the 2008 International Recommendations for Tourism Statistics or IRTS (United Nations Statistics Division, 2010), reflects this complexity by classifying a comprehensive but fragmented set of industries to tourism. This complexity poses challenges for many domains within official statistics as it requires a fine level of disaggregation of activity; the equivalent of ISIC² or NACE class level.³ For many published series, at least in Ireland, this level of disaggregation is not available.

Tourism, as a sector, is also unusual or even unique in that the unit of analysis tends to be the customer or ‘visitor’ rather than the service provider or producer. In large measure this is a consequence of the complexity noted above. Tourism activity and consumption expenditure tends to be dispersed across a wide arc of industries: transport, accommodation, catering, retail, culture and sports. In some cases tourism expenditure occurs well before the trip begins and payment is often deferred until well after the trip and as a consequence it can be very difficult to measure properly. The net result is that traditional tourism statistics have put greater emphasis on demand side surveys (i.e. on the visitor rather than on the service provider) as many tourism industries would not naturally consider themselves as such, and are not in a position to distinguish tourist and non-tourist activity. As a result, there has been relatively less focus on supply side statistics, and here the emphasis has been on arrival and bed-night statistics at ‘collective accommodation’.

For the reasons noted above, only two of the nine chapters in the 2008 IRTS are dedicated to supply-side and employment issues.⁴ While this is understandable, it has meant that tourism statistics have become very sector

² ISIC or the International Standard Industrial Classification is the United Nations system for classifying all economic activity. Class level corresponds with 4 digit level disaggregation.

³ NACE is the economic activity classification used by Eurostat (the European equivalent of ISIC). Class level corresponds with 4 digit level disaggregation.

⁴ Chapters six and seven.

specific and are consequently very difficult to compare with other economic sectors; ‘arrivals’ or ‘bed-nights’ do not mean much, and are not relevant, to anyone outside the tourism sector. The economic rationale for having a tourism sector is to provide jobs, generate incomes and profit and to support the national economy. Yet from a business or economy perspective the existing suite of tourism statistics say little about the overall performance of the sector. Equally, little is known or understood about the real contribution of tourism to national and regional economies (Kenneally and Jakee, 2012). This ‘isolation’ of tourism statistics was part of the reason why the UNWTO has invested so much effort in carefully developing the Tourism Satellite Accounts or TSA (United Nations and World Tourism Organisation, 2010) and ensuring their consistency with the UN System of National Accounts 2008 (United Nations Statistics Division, 2009) and the 6th and latest edition of the IMF Balance of Payments and International Investment Position Manual or BPM6 (International Monetary Fund, 2009). The TSA has put tourism on a comparable analytical footing with other economic sectors or industries from a macro-economic perspective, facilitating credible analyses and providing meaningful information to policy and decision makers.

At sub-national level, the challenges inherent in compiling national tourism statistics magnify. Not only can tourism not be identified owing to problems of sectoral disaggregation noted above, but furthermore, many of the sample sizes employed in traditional official statistical surveys cannot support sub-national breakdowns. Equally, the challenges of compiling a TSA multiply considerably below national aggregation (Frechtling, 2008; Jones, 2009; Jones et al, 2009). This poses a particular challenge for tourism as it is a very place specific or local phenomenon where the tourism product and the relative contribution to the regional economy can differ quite significantly from region to region.

There are however a range of data sources, not typically associated with tourism, already in existence from which a range of useful complementary tourism indicators can be derived that could overcome some of the challenges noted above, namely; structural business statistics (SBS), labour force surveys (LFS) and administrative and similar large public service datasets and structured commercial ‘big data’. This paper seeks to identify and harvest some of these data in order to address some of the supply side gaps that exist at both national and sub-national (regional) level. While SBS data are used, this paper will concentrate primarily on exploiting public service or administrative data. In many countries, including Ireland, traditional LFS cannot even at national level,⁵ provide robust estimates of employment at NACE Class level. For the same reason and also owing to gaps in coverage, many structural or annual business statistics cannot provide estimates of tourism activity, particularly at the sub-national level.⁶ So for the purposes of this paper, the acknowledged potential of SBS, LFS and structured ‘big data’, such as credit card or mobile phone data are not investigated or discussed in any detail.

The approach outlined in this paper is particularly relevant at a time when National Statistical Institute (NSIs) and National Tourism Authority (NTAs) budgets are contracting and are also under considerable pressure to reduce respondent burden (National Statistics Board, 2003; European Commission, 2009; Eurostat, 2009; Stoiber, 2009). The administrative data used or recycled in this paper already exist, making it an efficient approach where the only cost is the marginal costs of conducting new analyses. Furthermore the approach outlined in this paper complements the philosophy of the TSA, providing indicators that can be directly compared with those in other economic sectors but in this case at a micro rather than a macro-economic level.

This approach can also provide indicators at sub-national and regional level. This is important as the lack of regional data has prevented sub-national tourism indicators being developed and has retarded analysis in this domain. In turn, this has undermined the credibility of the sector. So, this approach can contribute to the INRouTe guidelines⁷ being developed in cooperation with the UNWTO on the establishment of a Regional Tourism Information System (R-TIS) that might combine official and un-official tourism data.

This paper is presented in four sections. The first section outlines the purpose of the paper and the general approach proposed. Section II presents some important definitions and concepts underlying the findings of the paper and outlines the main data sources used. Section III provides some illustrations of the type of data that can be compiled from this approach. The paper is then concluded in Section IV with a brief discussion of how this approach can be developed and extended.

⁵ See (Smith and White, 2012) for a good example of tourism statistics derived from Labour Force Surveys, when sufficient levels of detail are available.

⁶ See (Demunter and Dimitrakopoulou, 2012) for some examples of national level tourism statistics derived from Structural Business Statistics.

⁷ See INRouTe (2013) to view the first set of prototype guidelines.

SECTION I – PURPOSE AND GENERAL APPROACH

Purpose of the paper

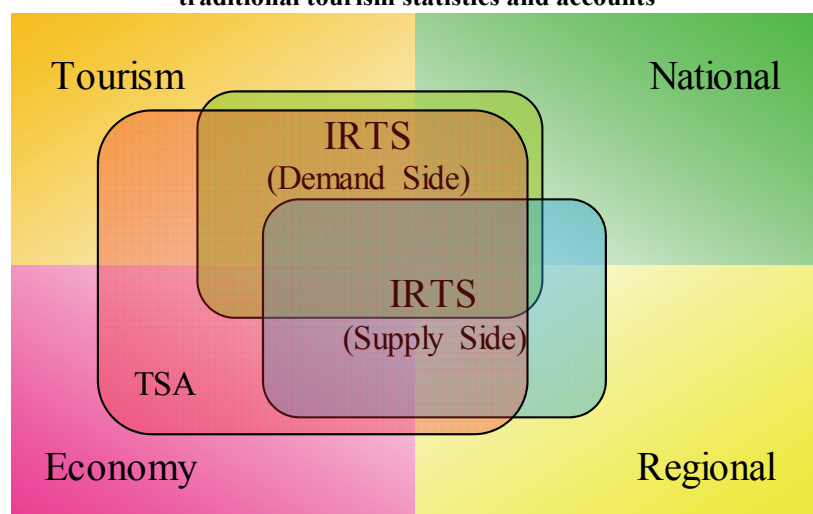

This paper has a number of purposes. Firstly, the paper proposes an approach to developing supply-side tourism statistics, where a gap exists or at any rate is a relatively undeveloped topic in the IRTS 2008. Although not outlined in any detail here, this approach can also be extended to tourism employment where the same criticism applies (UNWTO, 2008). So, the approach outlined can be viewed either as an extension or development to that already detailed in the 2008 IRTS or as a set of complementary indicators that sit alongside those recommendations (see Figure 1.1). Either way, what is proposed here, is consistent with the spirit of the IRTS – ‘Owing to the range of impacts and wide spectrum of stakeholders involved, there is a need for a holistic approach to tourism development, management and monitoring’ (United Nations and World Tourism Organisation, 2010, p.1).

Secondly, this paper proposes an approach that addresses, at least partially, one of the major challenges facing tourism statistics; how to compile robust sub-national statistics. The paucity of regional tourism data has been articulated many times (Deegan et al, 2004; MacFeely, 2006; United Nations World Tourism Organisation, 2013). The approach proposed here also dovetails or supports the policy initiatives being cultivated by Fáilte Ireland to develop national and regional destination management systems (Wall and MacFeely, 2011) and complement the approach taken by Galan and Bermejo (2006) to develop a set of destination indicators. Although the challenges of how to regionalise traditional tourism statistics are not addressed here, the paper nevertheless illustrates how policy relevant data for the tourism industries can be compiled for sub-national regions (or even small or atomic areas if required).

Thirdly, and finally, this paper articulates how other long standing criticisms or gaps in tourism statistics might be addressed. For example, business performance has typically been outside the scope of traditional tourism statistics, reflecting a wider knowledge gap regarding small business and entrepreneurial activity across regional economies (Mshenga et al, 2010; Eurostat, 2013). Specifically, this paper outlines an approach for analysing the performance and survival of tourism industries. Also, and very importantly, this approach to compiling additional or supplementary policy relevant national and regional tourism indicators can be done in a cost effective and burden free manner.

The general approach and the specific set of indicators proposed in this paper will facilitate or allow comparative analyses with other economic sectors (described in aggregate form in this paper as ‘non-tourism industries’) reducing the relative isolation of tourism statistics. This approach complements the aims and philosophy of the TSA (albeit from a micro rather than a macro perspective) in that these indicators can also be used to bridge the gap between tourism and other industries by providing comparable economic, business and social indicators.

Figure 1.1 – Relationship between Supply-Side Indicators and traditional tourism statistics and accounts

These supplementary or complementary indicators can be compiled at both national and regional level. At a national level, the supplementary indicators can be sourced from a variety of sources, including SBS, LFS, administrative data and ‘big’ data. At sub-national level, robust indicators are more likely, but not exclusively, to come from administrative or structured big data.

General Approach

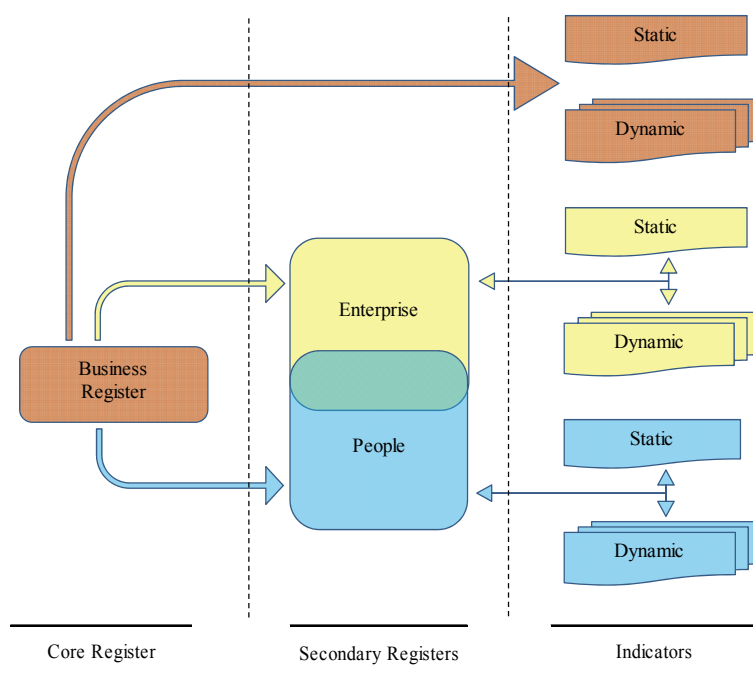

This paper illustrates how business registers can be used as a source to generate a new suite of supply side tourism indicators, notably: national and regional ‘tourism dependency ratios’ for variables such as number of enterprises, total employment and turnover. Other useful indicators, such as labour intensity, labour utilisation and regional enterprise demography and survival rates can also be derived. The use of business demography data is fundamental to this approach as standardised business register and demography data exist across all EU member states to comply with EU legislation. Similarly structured business registers exist in most other countries where reasonably developed statistical systems exist, making the approach outlined readily transferable and offering the opportunity to develop internationally comparable metrics by re-using already harmonised statistical sources. The scope of the data available from these sources is described in Figure 2 - ‘core register’.

While the ‘core register’ offers a framework to develop internationally comparable indicators, the structure, quality and organisation of public service or administrative data may otherwise vary enormously from country to country. Consequently, harvesting data from the ‘secondary registers’ i.e. other administrative data sources, may not be as readily transferable across countries (or perhaps regions in federal states). Nevertheless, the broad approach or logic of what is proposed in this paper should be transferable, even if the exact indicators vary from country to country.

For the purposes of this paper, registers and administrative data are bundled into two broad categories: enterprise data holdings and people data holdings (see ‘secondary registers’ in Figure 2). Of course, in some cases, such as taxation or social protection records, files may contain both person and enterprise information. But from an outputs perspective, or an analysis perspective, it arguably makes more sense to bundle data into enterprise (e.g. size, nationality, ownership type, profitability, business costs, prices, taxes, subsidies etc.) or people data (e.g. gender, age, income, nationality etc.). The people dataset could include employees, sole traders, directors and business proprietors.

Business demography statistics derived from the business register compiled and maintained by the CSO are central to the analyses presented in this paper. The scope or approach outlined in this paper can be extended to generate a more complex set of indicators by linking the ‘core’ business register at the unit-record level to other ‘secondary’ registers or administrative data sources. By incorporating other administrative data sources, for example environment or culture, other useful indicators on wellbeing or competitiveness could be derived (see Dupeyras and MacCallum, 2013). As already noted, for the purposes of exposition, the scope of this paper will focus on indicators that can be sourced from the ‘core’ register. Indicators from secondary registers are outside the scope of this paper, but for some examples of labour market indicators that can be derived from secondary tax and social welfare systems - see Delaney and MacFeely (2012) and Sakowski (2012).

Figure 1.2 – Linking Registers and Administrative Databases

From a statistical compilation perspective administrative data have a number of advantages, particularly when trying to produce sub-national data. Most importantly, key administration files such as taxation or social protection files typically have universal coverage, so even small, hard to reach areas and cohorts are included. In addition, if administrative data are well organised and structured, linkages or matching unit records over time may be possible, so that longitudinal or time-series datasets can be constructed (see MacFeely and Dunne, 2014). This allows analyses to move beyond static or point-in-time indicators to more dynamic or flow type analyses.

SECTION II – DEFINITIONS, CONCEPTS AND DATA SOURCES

What are administrative or public sector data?

This paper proposes harvesting administrative data to compile new tourism indicators, so it is important that the reader understand what is meant by the term administrative data. Blackwell defines administrative or public sector data as *‘information which is collected as a matter of routine in the day-to-day management or supervision of a scheme or service or revenue collecting system’* (National Economic Social Council, 1985: p78). Across civil and public services, huge volumes of administrative records are collected, maintained and updated on a regular basis. Considerable resources are expended by public services around the world in maintaining these records to ensure they are accurate and up-to-date. These data pertain to the wide range of administrative functions in which the State is involved, ranging from individual and enterprise tax payments to social welfare claims or education or farming grants. Typically these administrative records are collected and maintained at the lowest level of aggregation i.e. transaction or interactions by individual taxpayer/applicant/recipient with the state, making these data very rich from an analytical perspective.

This paper argues that with some additional effort, these records can be used or harvested to generate a new suite of indicators. The quality and complexity of the indicators will depend on how well organised and open public sector information is in any given country. The more organised and coordinated the data infrastructure is, the greater the potential for compiling statistics. Administrative datasets have a number of advantages; they are typically well established and in many cases, may be sufficiently large to provide robust, sub-national data. Like a census, administrative data offer considerable flexibility, as they typically capture their respective universe. So for example, the business register, which is constructed from several administrative data sources, can provide statistics at NUTS 4 level or even small or atomic area level, which is particularly useful, not only when analysing a sector such as tourism which is very place centric, but also as it provides a mechanism for adapting to changed regional administrations, such as those proposed in the most recent strategy for local government (Department of Environment, Community and Local Government, 2012). Such flexibility does not always exist with sample based data, as sample design takes into account existing administrative structures and cannot be easily adapted to take on board changed regional structures.

However, administrative data sources are not typically designed to align with statistical concepts. Consequently, extensive work may be required in order to derive usable statistical information. So there may be trade-offs; administrative or other very large datasets are realistically the only source of high quality, sub-national data available but these data may not align perfectly with tourism statistics concepts and may not be able to yield the traditional metrics associated with tourism. They can however yield a range of robust indicators, although not typically familiar to tourism analysts that are nevertheless very useful and policy relevant.

What are tourism industries?

As already noted the tourism sector is complex and is comprised of a heterogeneous bundle of diverse industries. The tourism industries, also referred to as tourism activities, are formally defined by the United Nations World Tourism Organisation International Recommendations for Tourism Statistics (United Nations and World Tourism Organisation, 2010) as activities that typically produce tourism characteristic products – see Appendix 1.

For the purposes of this paper, the definition of tourism industries is closely aligned but not exactly the same as that specified by the UNWTO (see Appendix 2 for definition of tourism industries used in this study). A one-to-one concordance between the UNWTO and NACE classifications was constructed in as far as was possible; a few differences exist between the two. The main difference arises where the business register in Ireland does not have sufficient granularity to identify very specialist ‘country specific’ tourism industries. There are a few areas where such specialist tourism products might exist: retailing, student education, specialist health or dental services. This problem will not be unique to Ireland and will most likely be an issue for any country that does not classify activity beyond ISIC or NACE class level. Consequently, the absolute value for the key indicators presented in this paper may be a slight underestimate of activity in the tourism industries. This underestimation should not be significant as the values associated with ‘retail trade of country-specific tourism characteristic goods’ and ‘other country-specific tourism characteristic activities’ are unlikely to be very large in Ireland’s case.

It is worth noting that Eurostat has also been examining the compilation of using alternative sources to develop supply side statistics (Demunter and Dimitrakopoulou, 2012). As part of this work, they are re-examining the scope of the tourism industries from a European perspective (Eurostat, 2013). For example, they are examining the value or relevance of including NACE Rev.2 5590 'Other Accommodation' as a tourism industry.

What are business demography statistics?

Business demography statistics provide data on the active population of enterprises in the State, including enterprise births (entries) and deaths (exists or failures) along with information on growth and survival (life expectancy) rates. These statistics are also used to generate indicators of entrepreneurial activity and the factors that enhance or impede it and to understand the contribution of newly-born enterprises to the creation of jobs.

Primary data sources

The source data for this study are Business Demography statistics, published by the Central Statistics Office in Ireland, in compliance with EU legislation.⁸ In turn, business demography statistics are sourced from the Business Register, which is a register of all enterprises that are active in the State, which is also compiled in adherence to EU legislation.⁹ These register data are assembled using information provided by the Revenue Commissioners covering all companies, individuals and partnerships that register for VAT, Corporation Tax or Income Tax or as employers. See Appendix 3 for more detail. The main variables available from the business register are location, legal status and size of enterprise, number of employees and persons engaged and total turnover.

Conceptual scope

Owing to the broad, heterogeneous mix of tourist products, tourism expenditure is dispersed across a wide set of industries. Hence the importance of the demand side perspective (sourced from visitors), as it is probably the only way to properly capture the full breadth of tourism consumption expenditure. The information in this paper is taken from supply-side (industry) sources and relate to the total activity in the tourism industries, irrespective of whether the products or services sold by these enterprises were consumed by tourists or not (i.e. total output of a Tourism Characteristic Industry (TCI) usually exceeds visitor consumption as some of the output generated by most TCIs are purchased by non-visitors). In other words the analyses do not quantify enterprise activity or employment generated by tourism demand – this is simply the measurement of jobs in the tourism industry not jobs created by tourism consumption. This is necessarily a restriction or limitation of many supply side sources. With the possible exception of those providing collective accommodation, tour operating services or perhaps chatty taxi drivers, most suppliers are unaware of whether their customers are tourists or not and do not make this distinction in their management or financial accounts. In order to measure the activity generated by tourism demand a Tourism Satellite Account is required.¹⁰

Equally, any secondary 'tourism' activity generated by 'non-tourism' industries will not be captured in these analyses. NACE activities of enterprises are codified to predominant activity and secondary activity is therefore not reflected. Although outside the scope of 'business economy' an example of relevant secondary activity would be tourism activity on farms, say horse riding. The National Farm Survey estimates that 2,000 farms/stables were engaged in secondary horse riding activities with approximately 2,400 persons employed on a FTE basis (CSO, 2008).

It is worth noting, for the sake of clarity, that the approach used in this paper is limited to direct employment in the tourism characteristic industries. Furthermore, it does not take into account indirect employment or tourism induced employment.

Tourism Dependency Ratios

Tourism Dependency Ratios (TDRs) should more accurately be called Tourism Industries or Tourism Sector Dependency Ratios but for ease of presentation are simply called TDRs. These ratios are simply standardised data; the ratio of the Tourism Industries to the Total Economy for a particular region (national or regional) and variable (Enterprise population, total employment or total turnover etc.).

⁸ Annex IX (A Detailed Module for Structural Statistics on Business Demography) of Regulation (EC) No. 295/2008 of the European Parliament and of the Council of 11 March 2008 concerning Structural Business Statistics (recast).

⁹ Regulation (EC) No. 177/2008 of the European Parliament and of the Council of 20 February 2008 establishing a common framework for business registers for statistical purposes and repealing Council Regulation (EEC) No. 2186/93.

¹⁰ Usually derived using Tourism Value Added Ratios.

$$TDR_N = \left(\frac{V^{TI}}{V^{TE}} \right)_N$$

Where:

TI are aggregate of the Tourism Industries for a particular region *N*;

TE is the Total Economy for region *N*;

V is the variable being compared (Enterprises, Employment, Turnover...);

N are the NUTS regions (NUTS 1, 2, 3 or 4).

SECTION III – STATISTICS AND INDICATORS

This section of the paper outlines some of the national and regional statistics that can be compiled from ‘core’ register or administrative data sources, namely business demography statistics. As already noted, this source provides a range of count (static) variables: location of enterprise; size of enterprise; number of employees; number of persons engaged; and total turnover. Flow or dynamic variables can also be derived, for example, survival rates. Importantly, this data source is compiled under EU legislation and so should be available across the EU-28. Furthermore, most extra-EU countries will have equivalent demography statistics or similar business registers, so this approach should be internationally transferable.

Table 3.1 – Summary Profile of Tourism Sector, 2011

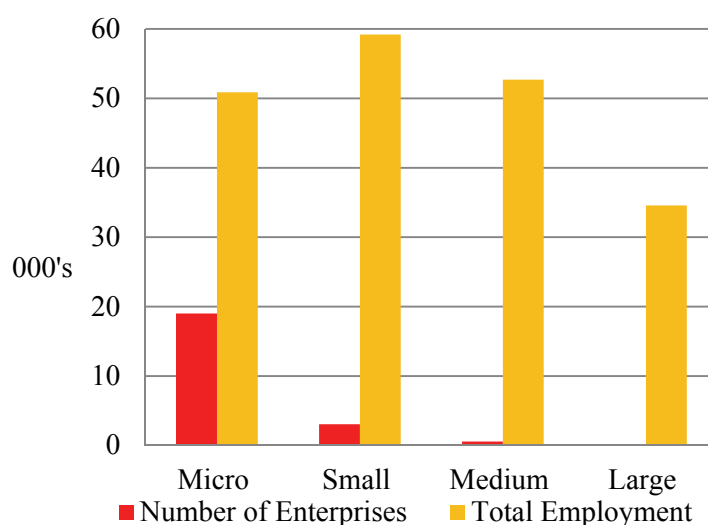

NACE Rev. 2 Section	Number of Enterprises <i>000's</i>	Total Employment <i>000's</i>	Total Turnover ¹ <i>€ Billion</i>	Total GVA ¹ <i>€ Billion</i>
Transportation and Storage (H)	1.9	27.1	7.6	2.6
Accommodation and Food Services (I)	16.3	146.0	7.9	3.0

Source: Business Register & Annual Services Inquiry

Table 3.1 presents a summary profile of the tourism industries in 2011. In brief, the tourism sector comprised of almost 23,000 enterprises, of which over 70% were in the accommodation and food industries (NACE Section I). These enterprises engaged a little over 197,000 persons and generated a total turnover of approximately €18.8 billion and a Gross Valued Added (Factor Cost) of €6.7 billion (or 4.6% of national GVA).

Figure 3.1 – Number of Enterprises and Total Employment by Employment Size Class in the Tourism Industries, 2011

The vast majority (98.8%) of Tourism Industries are SMEs, with only 38 of the 23,000 classified as large – see Figure 3.1. These SMEs account for 82% of employment in the Tourism Industries. Average employment per enterprise grows progressively with each size class, from an average of 3 persons per micro enterprises to an average of 910 per large enterprise – see Appendix 5.

Although Turnover is available from the business register, GVA is not, therefore the estimates of turnover and GVA presented in Tables 3.1 and 3.2 were sourced from the Annual Services Inquiry, so that the relative values of Total Turnover and GVA were consistent. The contribution of the tourism industries to national GVA of 4.6% seem reasonable, as the pilot Tourism Satellite Account (Deegan et al, 2004) estimated the contribution of tourism demand to national GDP at 3.5% in 2000. Given the conceptual differences in the two approaches, the estimates presented here seem plausible. The key indicators detailed in Table 3.1 can be compared with their economy wide equivalents to give a number of national ‘Tourism Dependency Ratios’. These ratios illustrate the importance of the tourism sector to the national and regional economies - see Table 3.2.

Table 3.2 – National Tourism Dependency Ratios (current prices), 2006 – 2011

	Unit	2006	2007	2008	2009	2010	2011

¹ Source: Annual Services Inquiry - (NACE Rev.2 90 & 91 were imputed)

² Source: QNHS - arithmetic average of quarterly QNHS

³ Source: QNHS - arithmetic average of quarterly QNHS

⁴ Source: Business in Ireland 2009 - 2011. 2008 derived from SBS. Scope is 'Business Economy' only

⁵ Source: NIE (2012) Table 2 - item 29. Scope is national economy

From Table 3.2 it is evident that average labour productivity in the tourism industries is considerably lower (GVA per FTE of €49,500) than for the economy as a whole (€89,700). However, it is worth noting that the labour productivity generated by the tourism industries is the same as that generated by Irish owned enterprises that export (CSO, 2013b).

FTE employment for the tourism industries was derived on the same basis as the economy wide measure published in the QNHS. The reduced dependency ratio for the FTE measure indicates the higher utilisation of part-time labour in the tourism industries relative to the labour market as a whole. This measure shows that the

real fall in labour utilisation between 2007 and 2011 has been greater than the simple head-count implies, closer to -24% than the -10% fall estimated by the Total Employment measure. Turnover and GVA for the tourism industries cannot be compiled prior to 2008 as NACE Rev.1.1 did not provide sufficient disaggregation to properly identify those industries within the services sectors. The values for these indicators are given in current prices.

Between 2006 and 2011, the broad pattern or trend of enterprise births and deaths experienced in the tourism sector were broadly similar with those of the wider business economy, although in relative terms Tourism Industry births exceeded those of the economy as a whole while deaths were marginally less - see Figure 3.2 and Appendix 6. As noted in Appendix 4, statistical deaths take two years to determine, and consequently, the data for enterprise deaths in 2011 are not yet available.

Figure 3.2 – Enterprise Births and Deaths (Index: Year 2006 = 100)

A good example of the type of dynamic or flow indicators that can be derived are enterprise survival rates. To derive these indicators, microdata are required, as are unique business identifiers that facilitate matching and tracking of individual enterprises, so that individual enterprise survival can be ascertained. Surviving enterprises can be sub-set into high and low growth (either defined by turnover or employment or a combination of both). In general terms, the survival rates of tourism industries have not been significantly different from those of experienced by non-tourism industries (see Table 3.3). For all industries, whether tourism or not, survival rates for each duration (1 Year – 5 Year) deteriorated between 2006 and 2009. There appears to have been some improvement in 2010. Of the 1,600 tourism enterprises that commenced trading in 2006, only 53% survived their five years of trading. This is broadly in line with the wider economy, where the odds of surviving the first five years of trading were roughly 50-50.

Table 3.3 – Enterprise Survival Rates, 2006 – 2011

Year of Birth	Number of Surviving Enterprises					Survival Rates					
	1	2	3	4	5	1	2	3	4	5	
	Year	Years	Years	Years	Years	Year	Year	Year	Year	Year

Source: Business Register

Regionalising administrative data

Although the business register covers the universe of active enterprises in Ireland, deriving regional aggregates requires care. The geographical breakdown for each enterprise is an approximation as no comprehensive administrative source with exact business location is currently available. Consequently, county activity is based on the address where enterprises have registered for taxation purposes, rather than where businesses actually operate from. In the vast majority of cases, the registration or administrative address and the location of HQ activity are one and the same. The problem noted above, causes more significant challenges when attempting properly to allocate employment to region. For single unit enterprises this is not an issue, however for larger enterprises with several local units or branches, estimates of regional employment will be less exact, as all employment is often attributed to the county where the head office is located. Typically, this gives an employment bias in favour of Dublin, the capital city. Enterprises with an 'Unknown' address are generally registered outside the Republic of Ireland. However, their employees are working in the Republic of Ireland, and allocating this employment to location may not always be exact.

In turn, the HQ bias may result in an overstatement of the importance of the tourism industries to regions outside Dublin as some sectors, for example, Distributive Trades, may have a greater regional distribution in terms of local units than tourism industries (i.e. tourism industries are by and large single unit enterprises and so their regional distribution should be quite accurate, whereas some other industries may have more local units that may distort the true relative importance at county level). Consequently, the derivation of regional Employment TDRs was done with considerable care as the HQ effect, which results in an overstatement of employment attributed to Dublin, had to be adjusted for. The number of persons engaged in Dublin in 2011 according to the business register was 599,000 compared to an equivalent labour force estimate of only 401,000,¹¹ a difference of 198,000 (or 33%). As a result, county Employment TDRs are likely to be overstated. This bias was adjusted for by matching 'Business Sector' employment from the business register and LFS for the Dublin region, which is both a NUTS 3 and NUTS 4 region. The residual was redistributed across the other counties on a proportionate basis.¹²

When the absolute data are mapped the dominance of the Dublin economy is immediately apparent but otherwise little useful information is illustrated. However if the data are standardised by region to derive TDRs, the data are more revealing, as the relative importance of the tourism industries to each region becomes apparent. In 2011, Enterprise and adjusted Employment TDRs ranged from 8.8% to 19.1% and 5% to 15.3% respectively – see appendices 7 and 8. County Meath is in the lowest cohort for both measures. Counties Donegal and Kerry are in the highest cohort for both TDRs. Map 1 (Enterprise TDRs) illustrates clearly that for Dublin, the number of tourism industries are relatively less important to that regional economy, as to most others. This is intuitive as Dublin, with a large urban centre with the most diversified industrial base, is relatively less dependent on tourism and the tourism industries compared with several other regions. Map 2 shows the importance of tourism employment to the counties along the western seaboard, the South-East and Dublin. The composition of employment in Dublin is quite different to that of the tourism industries in other counties. Dublin is less dependent on the traditional 'food and accommodation' but has significant numbers employed in Transportation and Storage, Administrative and Support Services and Arts, Entertainment and Recreation. Again this illustrates the diversity of the Dublin economy and in particular the importance of the airport, seaport and other tourism and sporting infrastructure.

¹¹ Average employment for 2011 in the Dublin region of 549,000 less NACE Sections A (Agriculture, Forestry and Fishing), O (Public Administration and Defence), P (Education) and Q (Human Health and Social work activities).

¹² As the QNHS cannot provide county level employment estimates, Dublin which is both a NUTS 3 and NUTS 4 level region, provided a bridge. The county patterns for the QNHS were estimated from the 2006 and 2011 Census of Population employment patterns.

Map 1 – Enterprise TDRs by County, 2011

Map 2 – Employment TDRs by County, 2011

The Turnover TDRs are quite erratic compared with enterprise and employment TDRs. For this reason, Turnover TDRs were averaged over 2009 – 2011 and are presented at NUTS 3 level in order to make the data more stable. Turnover TDRs ranged from a low of 3% in the South-West to highs almost of 9% in the West - see Appendix 9 and Map 3. The Turnover TDRs for the BMW (Border, Midlands and Western) and S and E (Southern and Eastern) regions contrast noticeably – 7.2% and 4.7% respectively.¹³ The low TDRs in the Dublin and the South-West reflect the high turnovers generated by non-tourism industries in Cork and Dublin. Equally, the high TDRs in the West, South-East and Midlands highlight the economic importance of tourism industries to less diversified regional economies.

Map 3 – Turnover TDRs by NUTS 3 Region, 2011

From a policy perspective these patterns are important as many the counties with the highest TDRs (particularly those along the western seaboard, midlands and South-East) are some of the most deprived counties in the State as measured by per capita Household Disposable Income i.e. less than 95% of State average (CSO, 2013a). Of particular interest from an Irish perspective are the implications for industrial, regional and employment policy, as these are the counties where multinational enterprises will be least keen to invest in as they do not have large urban centres with easy connectivity, ready supplies of workers, universities and research capacity (Clinch et al, 2002; Doring et al, 2006).

Regional births, deaths and survival rates can vary quite a bit. This is not very surprising as the number of enterprise births and deaths in any one individual county for any one year can be quite small and could be affected by a range of localised circumstances. Kaniowski and Peneder (2008) list a variety of factors, including seasonality, destination size and market structure, which may influence an enterprises chances of survival. Issues such as access to finance, access to market and global conditions and security could also be added. Figure 3.3 presents the 1 year, 2 year, 3 year, 4 year and 5 year survival rates for the tourism industries by NUTS 3 region. While the patterns are fairly similar across the regions, lower survival rates in Dublin are evident, where after five years only 48% of enterprises born in 2006 were still trading (compared with 58% in the mid-West).

¹³ See Appendix 9.

Figure 3.3 – Survival Rates by NUTS 3 Region

SECTION IV – CONCLUSION

Tourism statistics are difficult and costly to compile at a national level. At a regional level these difficulties and costs escalate and may be so prohibitive as to prevent their compilation altogether. At a time when National Statistical Institutes and National Tourism Authorities have contracting budgets, and are under pressure to reduce respondent burden, it is important that all available data sources are examined and utilised to the maximum extent possible. From a demand-side perspective, sub-national tourism statistics are complex and prone to error, as in addition to the usual recall problems, visitors often do not properly understand where they were or as Theroux (1992, p.18) famously put it ‘*Tourists don't know where they've been, travellers don't know where they're going*’. Realistically the traditional methods of compiling tourism statistics (i.e. from survey data) cannot provide robust, detailed, small area or regional tourism information and thus alternate approaches to compiling sub-national statistics and deriving indicators must be considered. In particular, administrative datasets relating to the tourism supply side or large commercial datasets arising from tourists’ digital footprints should be explored and exploited.

Historically, greater attention has been devoted to the demand side of tourism statistics. Thus, our understanding of tourism industries and employment is poor relative to other economic sectors of the economy. Although the IRTS 2008 point to the importance of administrative data and registers as a valuable source of data, the framework document is relatively quiet on specifics. This should not be surprising as until relatively recently, availability and access to administrative data was not possible in many countries including Ireland, and no doubt, this limited our understanding of the potential of these data. However with improvements in technology and information storage, the quality and accessibility of public sector data has been steadily improving. In this paper we argue that it is time to move beyond arrivals and bed-nights and exclusive reliance on collective accommodation statistics and begin harnessing the power of administrative data and registers.

The approach proposed in this paper has limitations, as does every approach, but many of the obvious downsides can be addressed with further work and research. Most notably, the indicators derived only measure total activity of the tourism industries, rather than activity created by tourism demand. Perhaps this is viewed as too heavy a price and not worth the effort. We take a contrary view and argue that policy relevant, internationally comparable indicators can be compiled from administrative data. Furthermore this approach can be supplemented by Tourism Value Added Ratios to generate tourism demand statistics. The approach proposed in this paper is also a mechanism to develop new and very rich statistics on employment in the tourism industries and the quality of that employment and associated earnings. These indicators can be used in their own right or be used as the basis for top-down adjustments to national estimates or periodic satellite accounts. These data could also be used to supplement composite tourism sustainability indices, such as those proposed by Fernandez et al (2009).

This approach only offers a partial solution to the supply-side gap as it will most likely not yield short-term indicators. The indicators derived from this approach are limited to annual and come with a time lag of roughly T+18 months. These are drawbacks to a sector with clear seasonal patterns. Nevertheless, for structural analyses, these data offer real potential. With some adjustments to short term indicators, such as the Monthly Services Inquiry compiled by the CSO, a monthly tourism production index could be compiled.

There are a number of advantages to utilising business registers and demography information; they provide a robust data source and are already compiled to support the wider body of business statistics and so are relatively inexpensive to use and impose no additional response burden on respondents or businesses. Furthermore, broadly comparable data should be available across the EU, as every member state must compile business demography information in compliance with EU Regulation No. 295/2008. This last point is important, as raw tax administration on their own may have gaps or biases arising from poor tax compliance. However EU member states, in compiling their business demography data, should have made any necessary adjustments.

The national and regional indicators presented in this paper are only a small illustration of the statistics and information that can be compiled and the data sources used are just an illustration of the data potentially available. By linking business demography statistics to other administrative data sources at a micro-level,¹⁴ such as social welfare or taxation data, a much wider suite of complementary national and regional statistics can be derived. For example, information on nationality, age, gender of employees and enterprise CEOs working in the tourism industries in each region, earnings and duration of employment are available to develop new indicators on *quality of work* in the tourism industries. Potentially even more sophisticated analyses could be facilitated, such as tracking spatial migration of temporary workers, lifecycle working patterns, or determining real labour costs.

The approach outlined in this paper is simple and straight forward. By harvesting existing data sources, both official statistics and administrative data, a large set of valuable, structural statistics that shed light on the supply-side of the tourism sector can be compiled on a comparable basis at regional, national and international level. These new indicators allow the tourism sector to be compared with other economic sectors, making the contribution of the sector to the national and regional economies more transparent. From a policy perspective this is important, as it reduces the isolation of the tourism sector and allows the interconnections and interdependencies with the wider economy to be better understood.

APPENDIX 1: UNWTO TOURISM INDUSTRIES/ACTIVITIES

Tourism industries, also referred to as tourism activities, are activities that typically produce tourism characteristic products.

Tourism characteristic products are those that satisfy one or both of the following criteria:

(a) Tourism expenditure on the product (either good or service) should represent a significant share of tourism expenditures (share-of- expenditure/demand condition)

(b) Tourism expenditure on the product should represent a significant share of the supply of the product in the economy (share-of-supply/demand condition). This criterion implies that supply of a tourism characteristic product would cease to exist in meaningful quantity in the absence of visitors (United Nations Statistics Division, 2010, p.40).

Tourism Activities/Industries	
1	Accommodation for visitors
2	Food & Beverage serving activities
3	Railway passenger transport
4	Road passenger transport
5	Water passenger transport
6	Air passenger transport
7	Transport equipment rental
8	Travel agencies and other reservation services activities
9	Cultural activities
10	Sports and recreational activities
11	Retail trade of country-specific tourism characteristic goods
12	Other country-specific tourism characteristic activities

APPENDIX 2: CONCORDANCE BETWEEN UNWTO TOURISM INDUSTRIES AND NACE REV.2

UNWTO Tourism Industries	NACE Rev.2
1 Accommodation services for visitors	NACE Rev.2
Hotels and similar accommodation	55.10
Holiday and other collective accommodation	55.20
Recreational vehicle parks, trailer parks and camping grounds	55.30
Other accommodation	55.90
2 Food and beverage serving services	
Restaurants and mobile food service activities	56.10
Event catering activities	56.21
Other food services	56.29
Beverage serving activities	56.30
3 & 4 Railway & Road passenger transport services	
Passenger rail transport, interurban	49.10
Urban and suburban passenger land transport	49.31
Taxi operation	49.32
Other passenger land transport n.e.c.	49.39
5 Water passenger transport services	
Sea and Coastal passenger water transport	50.10
Inland passenger water transport	50.30
6 Air passenger transport services	
Passenger Air Transport	51.10
7 Transport equipment rental services	
Renting and leasing of cars and light vehicles	77.11
8 Travel agencies and other reservation services	
Travel agency activities	79.11
Tour operator activities	79.12
Other reservation service and related activity	79.90
9 Cultural services	
Performing arts	90.01
support activities to performing arts	90.02
Artistic creation	90.03
Operation of arts facilities	90.04
Library and archives activities	91.01
Museums activities	91.02
Operation of historic sites and buildings and similar visitor attractions	91.03
Botanical and zoological gardens and nature reserves activities	91.04
10 Sports and recreational services	
Operation of sports facilities	93.11
Fitness facilities	93.13
Other sports activities	93.19
Activities of amusement parks and theme parks	93.21
Other amusement and recreation activities	93.29
Renting and leasing of personal and household goods	77.21
* Activities of sports clubs (93.12) excluded	

APPENDIX 3: ENTERPRISE DEMOGRAPHY

The population of active enterprises, for a given year, contains all enterprises that were active at any stage during the reference year. Enterprises are counted as active if they satisfy at least one of the following conditions. The enterprise:

- Paid VAT during the reference year;
- Employed persons during the reference year;
- Filed a Corporation Tax return for the reference year; or
- Filed an Income Tax return for the reference year with turnover of more than €50,000.

Although, in theory the Business Register should cover all economic activity in the State, in practice, coverage is not complete. The register, when classified to NACE Rev.2, includes the following NACE Sections:

B	Mining and quarrying;
C	Manufacturing;
D	Electricity, gas, steam and air conditioning supply;
E	Water supply; sewerage, waste management and remediation activities;
F	Construction;
G	Wholesale and retail trade; repair of motor vehicles and motorcycles;
H	Transportation and storage;
I	Accommodation and food service activities;
J	Information and communication;
K	Financial and insurance activities (excl. 64.20 <i>Activities of holding companies</i>);
L	Real estate activities;
M	Professional, scientific and technical activities; and
N	Administrative and support service activities.

Thus, Agriculture and non-market/Public services sections are excluded.

The geographical breakdown for each enterprise is an approximation because no comprehensive administrative source is currently available for business locations. Consequently, the county activity is based on the address where enterprises have registered for taxation purposes, rather than where businesses actually operate from. In the majority of cases, the registration or administrative address and the place of activity are the same. However, for some larger enterprises with several local units or branches, estimates of regional employment will be less exact, as all employment is attributed to the county where the head office is located. This gives an employment bias in favour of Dublin, the capital city. Enterprises with an 'Unknown' address are generally registered outside the Republic of Ireland. However, their employees are working in the Republic of Ireland, and allocating this employment to location may not always be exact. The register also draws a distinction between total employment (persons engaged) and employees. For the purposes of business demography, employees are defined as: 'Persons who are paid a fixed wage or salary, including those temporarily absent because of illness, holidays or strikes'. Persons working on a labour-only, sub-contract, basis will usually not be included in the sector sourcing the activity but rather in the sector selling the service - NACE 78.20 (Temporary Employment Agency Activities). A better measure of total labour input is Persons Engaged, which includes proprietors, partners and casual or temporary workers.

APPENDIX 4: ENTERPRISE BIRTHS, DEATHS and SURVIVAL

Enterprise Births

An enterprise birth is the creation of a combination of production factors with the restriction that no other enterprises are involved in the event. Births do not include entries into the population due to mergers, break-ups, split-off or restructuring of a set of enterprises. It does not include entries into a sub-population resulting only from a change of activity.

A birth occurs when an enterprise starts from scratch and commences activity. An enterprise creation can be considered a valid 'birth' if new production factors, in particular new jobs are created. If a dormant unit is reactivated within two years, this event is not considered a birth.

Calculation of Enterprise Births

The population of real births in each year was estimated using administrative data as follows:

All enterprises registered with the Revenue Commissioners, recording activity from a taxation perspective in the reference year, but none in the previous two years, are extracted as the population of potential births. From this population, all potential births employing more than 20 people in the reference year are checked, along with a sample of smaller potential births. This determines whether the enterprise is a real birth in the reference year, or if it is a takeover or company restructure of an existing enterprise. Validation is carried out using other administrative sources, internet searches, or direct contact with the enterprise.

Validation shows that typically, around half of all potential births are not actually genuine new enterprises. For large potential births, employing over 20 people, only the births that were confirmed to be real are included in the final figures. For smaller size births, the proportion of real births identified in the validated sample is used to weight the potential births to create an estimate of the number of total births.

Potential issues with measuring enterprise births in tourism related sectors

Some of the activities covered in the tourism related industries are associated with frequent changes of ownership, e.g. pubs and restaurants. It is likely that this results in a higher proportion of potential births that are not real births appearing in the administrative data. Consequently the number of enterprise births and employment in these births may be overstated in tourism related sectors.

Enterprise Deaths

An enterprise death is the dissolution of a combination of production factors with the restriction that no other enterprises are involved in the event. Deaths do not include exits from the population due to mergers, takeovers, break-ups or restructuring of a set of enterprises. It does not include exits from a sub-population resulting only from a change of activity. An enterprise is included in the count of deaths only if it is not reactivated within two years.

Calculation of Enterprise Deaths

All enterprises registered with the Revenue Commissioners, recording activity from a taxation perspective in the reference year but do not record activity in the following two years, form the population of potential deaths. Two years of data are required to exclude enterprises that are dormant for one year, but recommence activity in the following year. However, preliminary figures are released using just the following year's activity data. These preliminary figures include enterprises that later reactivate and are subsequently removed from the final figures.

As with enterprise births, samples of potential deaths are manually checked to eliminate takeovers and changes of administrative numbers that don't result in the real cessation of a business.

In Ireland the main administrative data sources for reference year $t + 1$ are not available until November of year $t + 2$. Preliminary data on deaths for year t are published once these data have been received and processed in year $t + 3$. The final data on deaths for year t are published in year $t + 4$.

Enterprise Survival

Estimates are provided for the number of new enterprise births that are still active in the years after their birth, along with the numbers of persons engaged in these enterprises in the year of birth, and in the year in which they survive.

Calculation of Enterprise Survival

All enterprises registered with the Revenue Commissioners, recording activity from a taxation perspective in the reference year.

All potential births that are still active from a Revenue Commissioner perspective in the year after their birth are considered the population of potential one year surviving enterprises. Adjustments are made to this population to account for potential births in this population that were not real births (see calculation of Enterprise Births) and also for enterprises that survived by take-over.

Similar calculations are used to estimate figures for enterprises that survive two, three, four and five years after their year of birth. The size class breakdown provided for the variables relating to survival is based on enterprise employment in their year of birth.

Potential issues with measuring enterprise survival in tourism related sectors

As noted above some tourism related industries are associated with frequent changes of ownership, which may result in an over estimation of births and new employment. In turn this may result in an under estimation of survival rates for the same sectors.

Business Demography Population Changes, Births and Deaths

The difference between the Business Demography enterprise populations in successive years is different from the number of new births minus the number of ceased enterprises. This is due to the method of calculating real births and deaths from potential administrative changes.

Enterprises in year $t - 1$ are matched with year t to identify potential births and deaths. Those in year t but not year $t - 1$ are potential births in year t , while those in year $t - 1$ but not in year t are potential deaths in year $t - 1$.

So the population in year t equals the enterprises that continued between years $t - 1$ and t plus the potential births in t and the population in year $t - 1$ equals the enterprises that continued between years $t - 1$ and t plus the potential deaths in $t - 1$. This means that the difference between the numbers of enterprises in t and those in $t - 1$ equals the potential births in t minus the potential deaths in $t - 1$.

However, typically around half of the potential births are not real births (they are registrations of administrative change, but no new business has actually been created). Usually a higher number of potential deaths are real deaths, but again many are due to administrative changes, and not the real closure of a business. So the difference between potential births in t minus potential deaths in $t - 1$ does not equal the numbers of real births in t minus real deaths in $t - 1$.

However, note that for years where the percentage of potential births that were real is fairly close to the percentage of potential deaths that were real, the differences between the potential figures will be close to the differences between the real figures.

**APPENDIX 5: NUMBER OF ENTERPRISES and TOTAL EMPLOYMENT
BY EMPLOYMENT SIZE CLASS, 2011**

NACE Rev. 2 Description	Micro (< 10)	Small (10-49)	Medium (50-249)	Large (250 +)	All
	<i>Units</i>	<i>Units</i>	<i>Units</i>	<i>Units</i>	<i>Units</i>
<i>Number of Enterprises</i>

FIRST VOTE OF THANKS PROPOSED BY CAEMAN WALL, FÁILTE IRELAND

Introduction

Before I say too much, I should explain what makes me fit to comment on the main paper. For the last three years I have been Fáilte Ireland's Head of Research and Evaluation and joined the company six years ago as an economist.

Fáilte Ireland has a strong research team and we are active domestically and internationally in sharing, developing and implementing best practice in our subject area. Hence, we talk at and attend conferences organized by bodies like the OECD, the UNWTO, the European Travel Commission and so on. In short, we keep a 'window open' to the world outside Irish tourism as it helps us to stay fresh.

The Challenge

I will start with a quick review of some concepts and terms familiar to those working in the tourism sector, but worth repeating:

*Tourism is defined by the activities of persons identified as visitors. A visitor is someone who is making a visit to a main destination outside his/her usual environment for less than a year for any main purpose [including] holidays, leisure and recreation, business, health, education or other purposes....As a demand side phenomenon, the economic contribution of tourism has to be approached from the activities of visitors.*¹⁵

The fact that tourism is demand side defined gives rise to a number of challenges when it comes to understanding tourism and its impact:

- As the main paper points out, tourism is unusual in that the unit of analysis tends to be the visitor rather than the service provider or producer.
- In relative terms, tourism is a 'blind spot' in the national accounts and it is very difficult to compare with other economic sectors. Hence, the UNWTO's efforts to develop Tourism Satellite Accounts.
- The sector is more open than most to being subject to impact studies of questionable merit owing to the relative lack of supply side metrics. For example, looking at some recent policy review submissions, the phrase 'visitor economy' seems to have caught the imagination of sectoral representative groups. As far as I can tell, the phrase 'visitor economy' was coined by Visit Britain.

These issues are not of academic interest to me; they are practical challenges for me and for Fáilte Ireland.

The Policy Context

Fáilte Ireland is Ireland's national tourism development authority, established to guide and promote the development of tourism as a leading indigenous component of the economy. To this end Fáilte Ireland, working in partnership with the tourism industry, provides an extensive range of services and business supports specifically designed to develop and sustain Ireland as a high-quality and competitive tourism destination.

An important area of focus is destination development, the logic being that:

*"The limited resources available to Fáilte Ireland must be targeted at those parts of the country where there is strong tourism activity and where, consequently, there are viable networks of tourism enterprises ... A key focus of this strategy [is] to concentrate efforts on the important tourism destinations and ensure that they are well positioned to take advantage of an upswing in international tourism."*¹⁶

Thus, Fáilte Ireland undertook to identify the country's most important tourism destinations (and then work to support those destinations in attracting more visitors and tourism revenues). This was an onerous task given the challenges noted above.

Owing to data limitation, the approach adopted differed from that of the main paper. In identifying priority destinations, the primary factors taken into consideration were:

¹⁵ Extracts from IRTS 2008, paras 1.9 and 2.9 For more see <http://unstats.un.org/unsd/tradekb/Knowledgebase/IRTS-2008>

- 1) The Supply Side: Based on the location of various clusters of tourism businesses and attractions. Fáilte Ireland's Tourism Content System (TCS) was used to identify supply side clusters. The TCS is the backend database for the consumer facing Discover Ireland website and contains approximately 16,000 'features' such as accommodation stock, attractions and activities. Data from the TCS was mapped using GIS software, and relative densities of tourism product were identified and mapped.
- 2) The Demand Side: Based on locations where international visitors stay, gathered from exit interviews with 30,000 departing overseas visitors over three years.

The Paper's Value

My colleagues and I were very grateful to the authors as earlier versions of the work presented today allowed us to independently validate our findings. The tourism hotspots identified via their Tourism Dependency Ratios (TDRs) largely correlate with the distribution of tourism ascertained through our work.

As validation can be a two way process, I should also say that the results presented regarding the size, scale and scope of the tourism sector feel right to us and are broadly consistent with the findings of other research with which we are familiar.

Taking a wider view, the innovative approach presented makes a number of important contributions at a national and international level. This is not just a personal view, a recent UNWTO publication¹⁷ called this work pioneering. These important contributions include the following:

- The linked administrative data approach enables comparative analyses with other economic sectors at a macro and micro level. While the ability to make macro level comparisons was already enhanced by the introduction of Tourism Satellite Accounts, the proposed approach better facilitates comparative analyses at sub-national level.
- It generates a range of robust and readily understood business and social indicators at regional level. The development of TDRs is a particularly novel way of presenting the results. TDRs allow policy makers, and others, to understand better the relative importance of tourism to particular regions.
- The linked administrative data approach is applicable across the EU drawing as it does on business demography data compiled under a common framework. Over the last two years, I have attended several tourism research conferences at which working papers were presented by those looking to use the linked administrative data approach developed by the authors for different countries and to adapt it to different settings.
- The robust and repeatable approach, developed within UN and Eurostat guidelines, reduces the scope for impact studies of questionable merit by filling information gaps with solid evidence-based analysis. The paper is also very clear and unambiguous in drawing a distinction that is not made often enough between (a) tourism industries and (b) economic activity created by tourism demand. It often seems people, knowingly or otherwise, talk of the former when they mean the latter.

In summary, the significant contribution made by Jillian Delaney and Steve MacFeely is to reduce the relative isolation of the tourism sector and to allow its interconnections and interdependencies with the broader economy to be better understood.

**SECOND VOTE OF THANKS PROPOSED BY JIM DEEGAN,
DEPARTMENT OF ECONOMICS AND NATIONAL CENTRE FOR TOURISM POLICY STUDIES,
UNIVERSITY OF LIMERICK**

Mr Chairman, ladies and gentlemen. I would like to thank the organisers for affording me the opportunity to respond to the paper this evening and from the outset to offer my sincere congratulations to Jillian and Steve for a very impressive piece of research. I have no doubt that the ideas and methodological approach developed during what I am sure was a true "labour of love" will be adopted by many researchers and policymakers in tourism across the world for years to come. In the time afforded to me I would like to confine my comments to the following:

¹⁷ IRTS 2008 Compilation Guide (Draft). Online at <http://unstats.un.org/unsd/statcom/doc14/BG-Tourism.pdf>

- Why it is important we devote time and effort to improve our understanding of the role of tourism in the economy and
- Like Jillian and Steve to consider how innovative methodologies and the use of ICT can enhance our understanding of the importance of tourism.

The paper presented tonight is most welcome because it puts a focus on improving our understanding of how tourism features in the macroeconomy and importantly does so in a manner that allows tourism to be compared with other sectors. Until relatively recently, tourism, as a fragmented, heterogeneous set of industries was largely invisible in national statistics across the world. In this context, the adoption of non-standard economic metrics by those in tourism was difficult for non-tourism people and policymakers to understand and the absence of direct comparators for tourism estimates undermined the sector as a focus of concern for economists and policymakers. Undoubtedly, the production of exaggerated multipliers and sometimes outrageous estimates of the economic impact of tourism by lobbyists only served to re-enforce a malign attitude to the sector amongst mainstream economists and policymakers. So, while there was clear evidence since the 1950s of a near uninterrupted growth in world tourism traffic volumes the accompanying focus by economists and statisticians to understand the true economic importance of the sector was more remarkable by exception than the norm. In the absence of detailed information, statistical offices across the world contented themselves to meet the mandate of producing a figure from tourism as a constituent of the balance of payments of a country.

The failure to account for tourism in national accounting and the reasons why have been well rehearsed by myself and others and will not be addressed in detail tonight. Suffice to say that these failures have been a worldwide phenomenon and importantly the heterogeneous nature of the sector has been a major constraint. Importantly, there is also a political economy dimension to the problem. In essence, politicians require votes and resultantly it is far easier to identify and connect with “homogenous” rather than “heterogeneous” actors in the economy. An easy way to understand this phenomenon is to reflect on the size of the European budget allocated to farmers via the political lobbying process.

Despite the foregoing, the recognition that the world needed a better methodological framework to measure and understand tourism had begun in the late 1970s and after 20 years of debate amongst statisticians at the United Nations, culminated with the agreement of the methodological framework required for the Tourism Satellite Account (TSA). Essentially, the TSA brings tourism in to the national accounts by the provision of a methodological framework consisting of ten standardised tables. The TSA brings the demand and supply of tourism together in a framework that mainstream statisticians and economists can engage with. As such, the TSA provides the comparative framework for tourism that for so many years had been absent.

Since the early noughties, many countries across the world, including Ireland, have made some strides to develop a TSA. At this point I must declare my involvement as both an advocate and team leader of the group that developed Ireland’s pilot TSA. The project *inter alia* identified some data gaps but in general Ireland’s statistical system compared favourably to others across the world. Most particularly, the pilot study identified the vital importance of “Tourism day visits” and the need to augment our understanding of tourism expenditure by the introduction of “expenditure diary studies” as an addendum to the traditional “recall” method. Like tonight’s paper, the main work involved in the construction of Ireland’s TSA was simply the hard endeavour of experienced researchers who are familiar with national accounts. Having been one of the advocates of a TSA, I would hope that the current ongoing review of Tourism Policy initiated by the Minister for Transport and Tourism will recommend that a TSA becomes a regular output of the work of the CSO.

The paper presented this evening put a focus on how supply side statistics can improve our understanding of tourism in the economy. While the authors correctly identified some limitations of this approach it is clear that there are wide ranging and important outcomes to emerge, not least the development of Tourism Dependency Ratios and the clear identification of how tourism is vital to many disadvantaged parts of the country. Yes, the findings identify what we may have thought but having this confirmed by robust data is critically important for a sector so often assumed to be deficient in hard core information.

Today, the use of ICT in our society is pervasive and this provides a significant opportunity to enhance our understanding of human behaviour. While there is legitimate concern that data security must be handled and monitored very carefully it is also increasingly clear that Smartphone users are freely generating and sharing massive amounts of data that can be used to inform our statistical system. Already, the use of phone technology to inform us about the location of tourists is well advanced.

For many years, colleagues and I at the University of Limerick have been experimenting with the use of tourism diaries to generate information on the detailed daily expenditure and spatial patterns of tourists. In more recent years this work has been extended to a mobile phone application and soon one of the major barriers to the retrieval of vital data - "roaming charges" will be eliminated. We are living in the era of "big data" and once we remember that issues such as "sample error" and "sample bias" occur in big as well as small data sets our understanding of many issues can be immensely improved. Of course, as recent evidence of the collapse of "Google's Flu Trends" shows we should caution that data users must not confuse correlation and causation.

So what can we conclude from all this. Firstly, our understanding of the true economic importance of tourism in Ireland, as in most other countries, has been and remains poor by traditional national accounting standards. In Ireland's case, the available information reveals that tourism was far more important in Balance of Payments terms in the post-war years 1946, '47 and '48 than agriculture yet the sector received far less policy attention than other sectors. In the late 1980s and again today the available data suggests that tourism remains one of the most significant contributors to employment growth. It is also clear from the work presented this evening that tourism is vitally important to the most disadvantaged parts of the country and all forecasts for the future of the location of economic activity suggests that this will continue.

From a review of policy documents since the establishment of the Irish State it is clear to me that tourism has not been afforded a consistent and strategic role to the creation of "high value added" employment in Ireland. Importantly, it is interesting to note that "outside commentators" have consistently expressed a view for many years that Ireland should put far greater focus on tourism as a strategic focus of economic development. Our failure to do so may reflect an absence of national confidence and the remnants of a "neo-colonial" legacy whereby tourism is associated with a form of servitude. Undoubtedly, the absence of hard data and the exaggerated claims of economic impact by industry lobbyists certainly contributed to the poor image of the industry amongst conservative economists and policymakers. Of course, the perception that tourism was simply low paid jobs with little connection to high value added sectors did not help but of course this is increasingly incorrect. If you do not believe me just think of the activities of a person both during the phase before a holiday decision is made and once they arrive at the destination. The international forecasts for tourism suggest the continued growth of the sector as a major component of the "leisure society" and Ireland is well placed to take advantage of this if we become far more aggressive in developing an understanding of how and what tourism can contribute to our economic development. We need to embrace all possibilities to enhance our understanding of the sector and that is why I am so happy to endorse Jillian and Steve's paper as an important contribution to this endeavour.

DISCUSSION

Bill Keating: I would like to congratulate the authors on developing this innovative approach to measuring the impact of the tourism sector and on a very interesting paper. As the proposer of the vote of thanks has said, the findings of the paper pass the simple test of being in accordance with common sense when you see the counties who are shown as having the highest percentage of employment in tourism. Having said that, I am sure Professor Deegan is right in his criticism of exaggerated multipliers, etc. in the past. In this paper, the authors are very clear on what is covered and is not covered in the statistics produced in their paper. The industries they call the "Tourism Sector" do not deal only with tourists but, on the other hand, do not include the effect of downstream employment. I would hope people in the sector will use these data bearing these caveats in mind. I think the data on survival rates is especially interesting to the extent that it points to 2010 as being the year in which enterprise survival rates really fell way. When talking about survival rates, it is worthwhile reading the definitions of births and deaths in Appendix 4. Unfortunately, I have found from experience over the years that many data users do not familiarise themselves with relevant definitions.

Patrick Paul Walsh: I would like to congratulate the authors on a very nice paper. The approach works with supply side data classified by sectors (NACE codes) that clearly would be affected by tourism but not a hundred per cent. It is not only tourists that use taxis, restaurants, and hotels. Would there be merit in getting demand side data to model how correlated the firm activities are inside these sectors to demand or even seasonal cycles. It seems that supply indicators in non-tourist sectors seem to have similar cycles. Could it be that business activity in general can drive a good proportion of the activity in the tourist sector in terms of conferences, meetings, and daytrips? The idea is to do a few robustness tests around the supply side statistics in terms of their correlation around tourist, business or even education cycles of activity.

Zienn Mottiar: I would like to congratulate the authors on a paper that will be extremely valuable in terms of evaluating the importance of tourism to Ireland, comparing tourism with other sectors and examining tourism from a regional perspective. My question is whether the data can be produced at town level, as often in tourism

it is these smaller areas that we are analyzing. Indeed with the development of products such as the Wild Atlantic Way it is groups of villages and towns which cross county lines that we need to analyze in order to determine tourism impact.

Raymond Keaney: I congratulate Jillian and Steve on their excellent paper. It makes a very valuable contribution to our understanding of the real significance of tourism to the Irish economy. One of the major gaps in our current tourism infrastructure relates to our lack of a systematic, cohesive approach to the collection, dissemination and use of quality data and insights to drive our key strategic decision-making processes. Tourism needs robust research to inform policy, to measure industry performance and to understand the value of government interventions. However, there is no formal budget line for tourism research in Ireland. By comparison, the agri-food sector received €641 million for research under the Science, Technology and Innovation programme in the NDP 2007-2013. Similarly, there is no specific tourism research budget line in Ireland's research and innovation programme 2014-2020. As the composition of Ireland's economy shifts to internationally traded services, tourism has a key role. In this context, data collection on tourism must become a priority and appropriate resources, both human and financial, ought to be put in place.

John FitzGerald: This paper is an excellent use of linked administrative data. It is only through using such data that an interesting picture of the Tourism related sector can be developed. It would be useful to express the turnover of the sector as a ratio of exports of tourism. This would give a good picture of the relative roles of tourism exports and other domestic demand in driving the sector. It would also be useful to show the contribution of the sector to GNP, not just value added. For Irish firms this is value added whereas for foreign firms it is the wage bill, possibly with an allowance for corporation tax if foreign profits are large. I suspect that in this sector the GNP effect will be close to GVA whereas in much of the tradable sector this is not the case. The data on births, deaths and survival are shown for the tourism sector and the rest of the economy. It would be interesting to have a three-way split – building (where I would expect the highest death rate), tourism, and the rest of the economy. The data on Full time Equivalent (FTE) employment are very interesting – a bigger fall in FTE than in overall employment. It would be interesting to show this for the economy as a whole. Big data has many advantages but care needs to be taken to ensure it is not seen as oppressive. Using their mobile phones to track tourists could be counter-productive.
